GIRDER DESIGN

Design

DESIGN PROCEDURE:

1. The prestressed I-girder should first be designed assuming that the contractor will vary the joint filler supporting the panels on the girder flange. This assumption will maintain the minimum slab/panel combination thickness of 8.5" and will eliminate the possibility of increased load due to varying slab thickness.
2. With the girder designed and the camber and haunching dimensions calculated, the girder should be checked assuming the contractor will use a constant 3/4" joint filler. This will cause the slab thickness to vary due to the camber of the girder, increasing the load. This additional load shall be placed as a concentrated load at the 1/8 point from each end of the girder from centerline of bearing.

An example of how this concentrated load could be calculated follows:

$W_{load} = (A)(0.15 \text{ kips/cubic ft.})$ determine the concentrated load * to girders by distributing the W_{load} transversely across the girders. (Use the Girder Reactions Program.)

* This load shall be positioned at the 1/8 point from centerline Bearing.

If the minimum haunch is greater than the 3/4" Joint Filler, the additional haunch shall be included in the slab thickness as a uniform load.

If the use of these loads causes the girder design to change, it shall be the responsibility of the designer to determine if the camber and haunching should be recalculated.

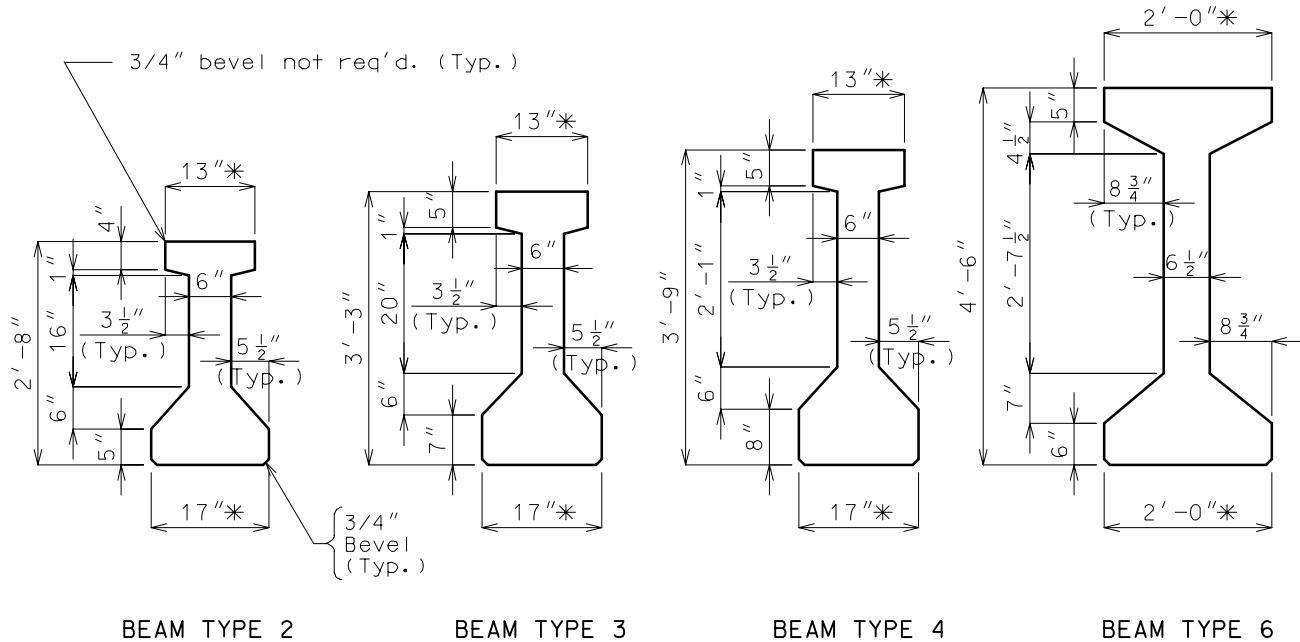

The bearing design calculations should use a combination of the heaviest loads and the lightest loads to ensure both the minimum and maximum dead load requirements are met.

GIRDER DESIGN (CONT.)
GEOMETRIC DIMENSIONS:

Design

The ratio of the depth of girder to span length will in general be not less than 1/18. (For estimation purposes only, see Table on page 1.1-8)

The cross sectional dimensions of the girder will be one of the following:

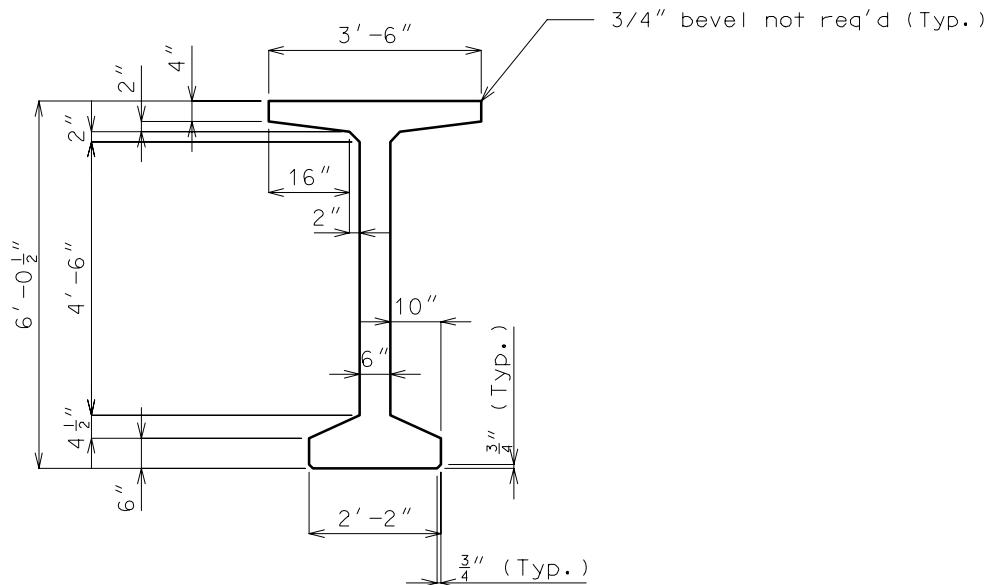

BEAM TYPE 2

BEAM TYPE 3

BEAM TYPE 4

BEAM TYPE 6

BEAM TYPE 7

* If the web is required to be increased, then the top and bottom flanges are to be increased by the same amount. (1" increments 2" max.). (See Development Section for A and I values.)

GIRDER DESIGN (CONT.)

GEOMETRIC DIMENSIONS (CONT.):

Design

Girder Analysis (Continuous Span Series)

Stresses due to dead load weight of slab, girder, diaphragms, haunch and forms will be based on simple spans from £ to £ of bearings. See Section 3.30 for weights to girders.

Stresses due to dead load weight of curbs, parapet, rails, future wearing surface and outlets will be based on continuous composite spans with loads equally distributed to all girders. The span lengths used in these computations will be based on the distance from the £ of the bearing at the End Bent to the £ of the Int. Bent, and from £ of Int. Bent to £ of Int. Bent.

Stresses due to live load plus impact will be based on continuous composite spans whose lengths are described above for curbs, etc.

The analysis will be made on the basis of transformed areas of all steel (both strands and bars) in the section using concrete with n=6.

In composite design, allowances shall be made for the difference in modulus of elasticity of slab and girder by using the effective slab area as specified for concrete T-Beams as given in the current AASHTO Specifications, multiplied by the factor (E_{slab}/E_{girder}). The area shall include the transformed area of all longitudinal reinforcing bars within the effective width. The 1" integral wearing surface shall not be used in the effective slab depth.

Effective Flange Width

The effective flange width for Beam Types 2,3,4 & 6 should be calculated using AASHTO 8.10.1. For Beam Type 7, the effective flange width should be calculated using AASHTO 9.8.3.

GIRDER DESIGN (CONT.)

CONTINUITY AT INTERMEDIATE SUPPORTS:

Design

Continuity will be obtained at intermediate supports by pouring a concrete diaphragm monolithic with the deck slab and encasing the prestressed girders. Reinforcing bars will tie the slab, diaphragms and girders together.

Reinforcing bars, $f_y = 60,000$ psi, will be placed in the deck slab for tensile steel.

The ultimate negative moments should be 2.17 times the maximum live load moments including impact and 1.3 times moments for future wearing surface and dead load of curb, parapet or safety barrier curb and bridge rail.

The area of longitudinal reinforcing steel at the centerline of the intermediate bent should be determined on the basis of a cracked section. This area of reinforcing bars is to be provided by adding additional bars between the normal longitudinal bars at the top of the slab. #8 maximum bar size for additional bars over bents.

These special negative moment reinforcing bars should be ended by one of the following criteria (whichever is greater):

- (1) Where the stress on the normal longitudinal reinforcing bars does not exceed 24,000 psi, as based on a cracked section, plus 15 bar diameters or development length. (See page 1.1-9 this section for example)
- (2) Not closer to the centerline of the intermediate bent than 1/10 of the span. (8' min.)

The concrete stress at the bottom of the girder should be checked at a point 70 strand diameters plus 9 inches from the centerline of the intermediate bent to see that the total compressive stress due to prestress and negative moment does not exceed 3,000 psi. (AASHTO. 9.7.2)

The positive moment at the intermediate bent should be provided for by extending the top two rows of the top strands (both straight or deflected) and if available, the number of bottom strands indicated in Tables 3.55 1.1-1 & 3.55 1.1-2 (on page 1.1-6B) bent to form a right angle hook.

GIRDER DESIGN (CONT.)

Design

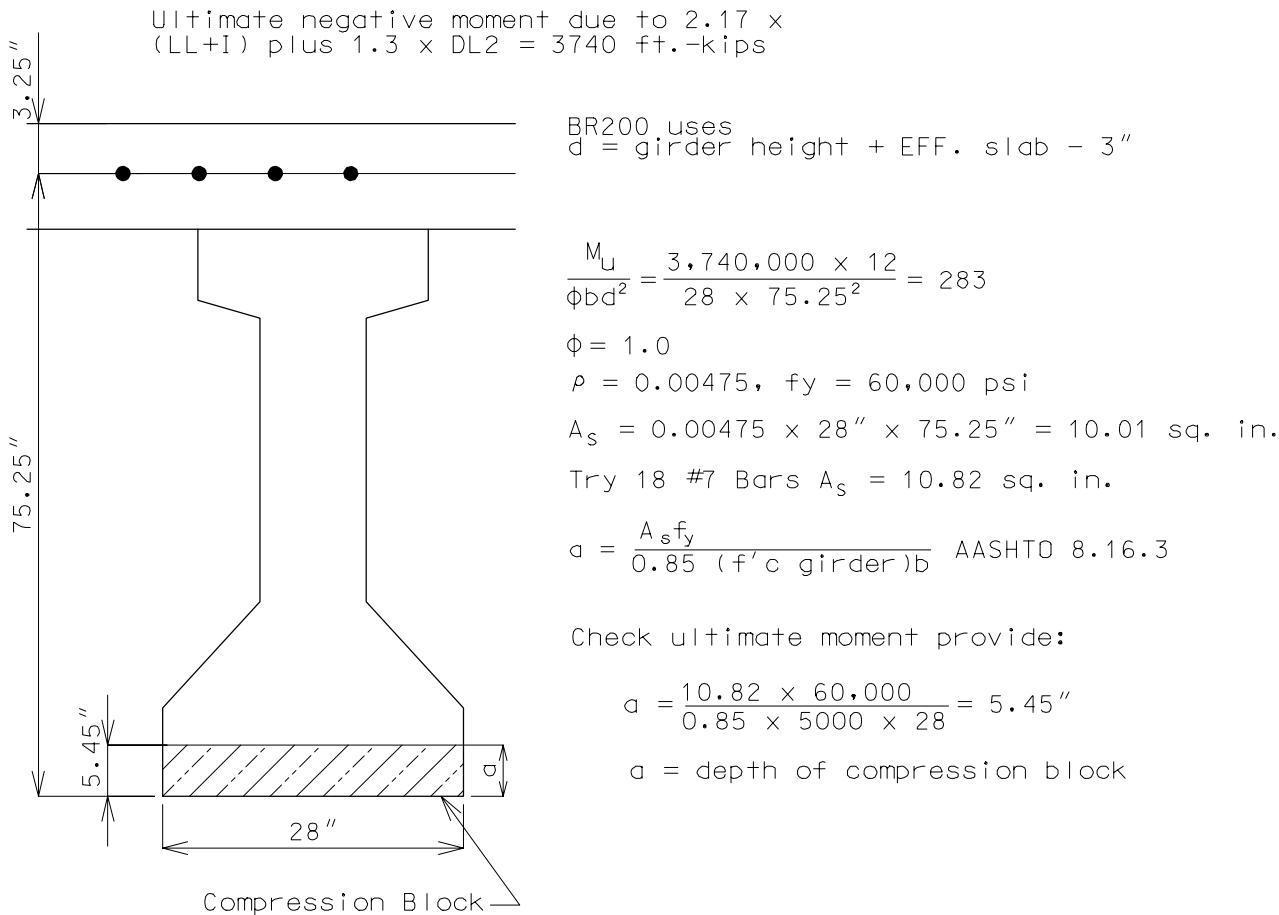

CONTINUITY AT INTERMEDIATE SUPPORTS: (CONT.)

Design of Negative Moment Reinforcement:

Since most of the dead load moments are carried by the beam acting as a simple span, the negative design moment over piers is the live load plus impact moment. In most designs, the dead load applied after continuity is achieved should also be considered in the negative design moment. The effect of initial precompression due to prestress in the precast girders may be neglected in the negative moment computation of ultimate strength if the maximum precompression stress is less than $0.4f'_c$ and the continuity reinforcement is less than 1.5 percent.

It will usually be found that the depth of the compression block will be less than the thickness of the bottom flange of the precast girder. For this reason, the negative moment reinforcement required can be determined by assuming the beam to be a rectangular section with a width equal to the bottom flange width of the girder. Due to the lateral restraint of the diaphragm concrete, ultimate negative compression failure in the PCA tests always occurred in the girders, even though the diaphragm concrete strength was about 1000 psi less than that of the girder concrete for this reason, it is recommended that the negative moment reinforcement be designed using the compressive strength of the girder concrete.

Design Example (*) (See chart on following page. The arrows on chart apply to this design example.)

Note depth of compression block < bottom flange thickness.

$$M_u = A_s F_y \left(d - \frac{a}{2} \right) = 10.82 \times 60,000 (75.25 - 2.725)$$

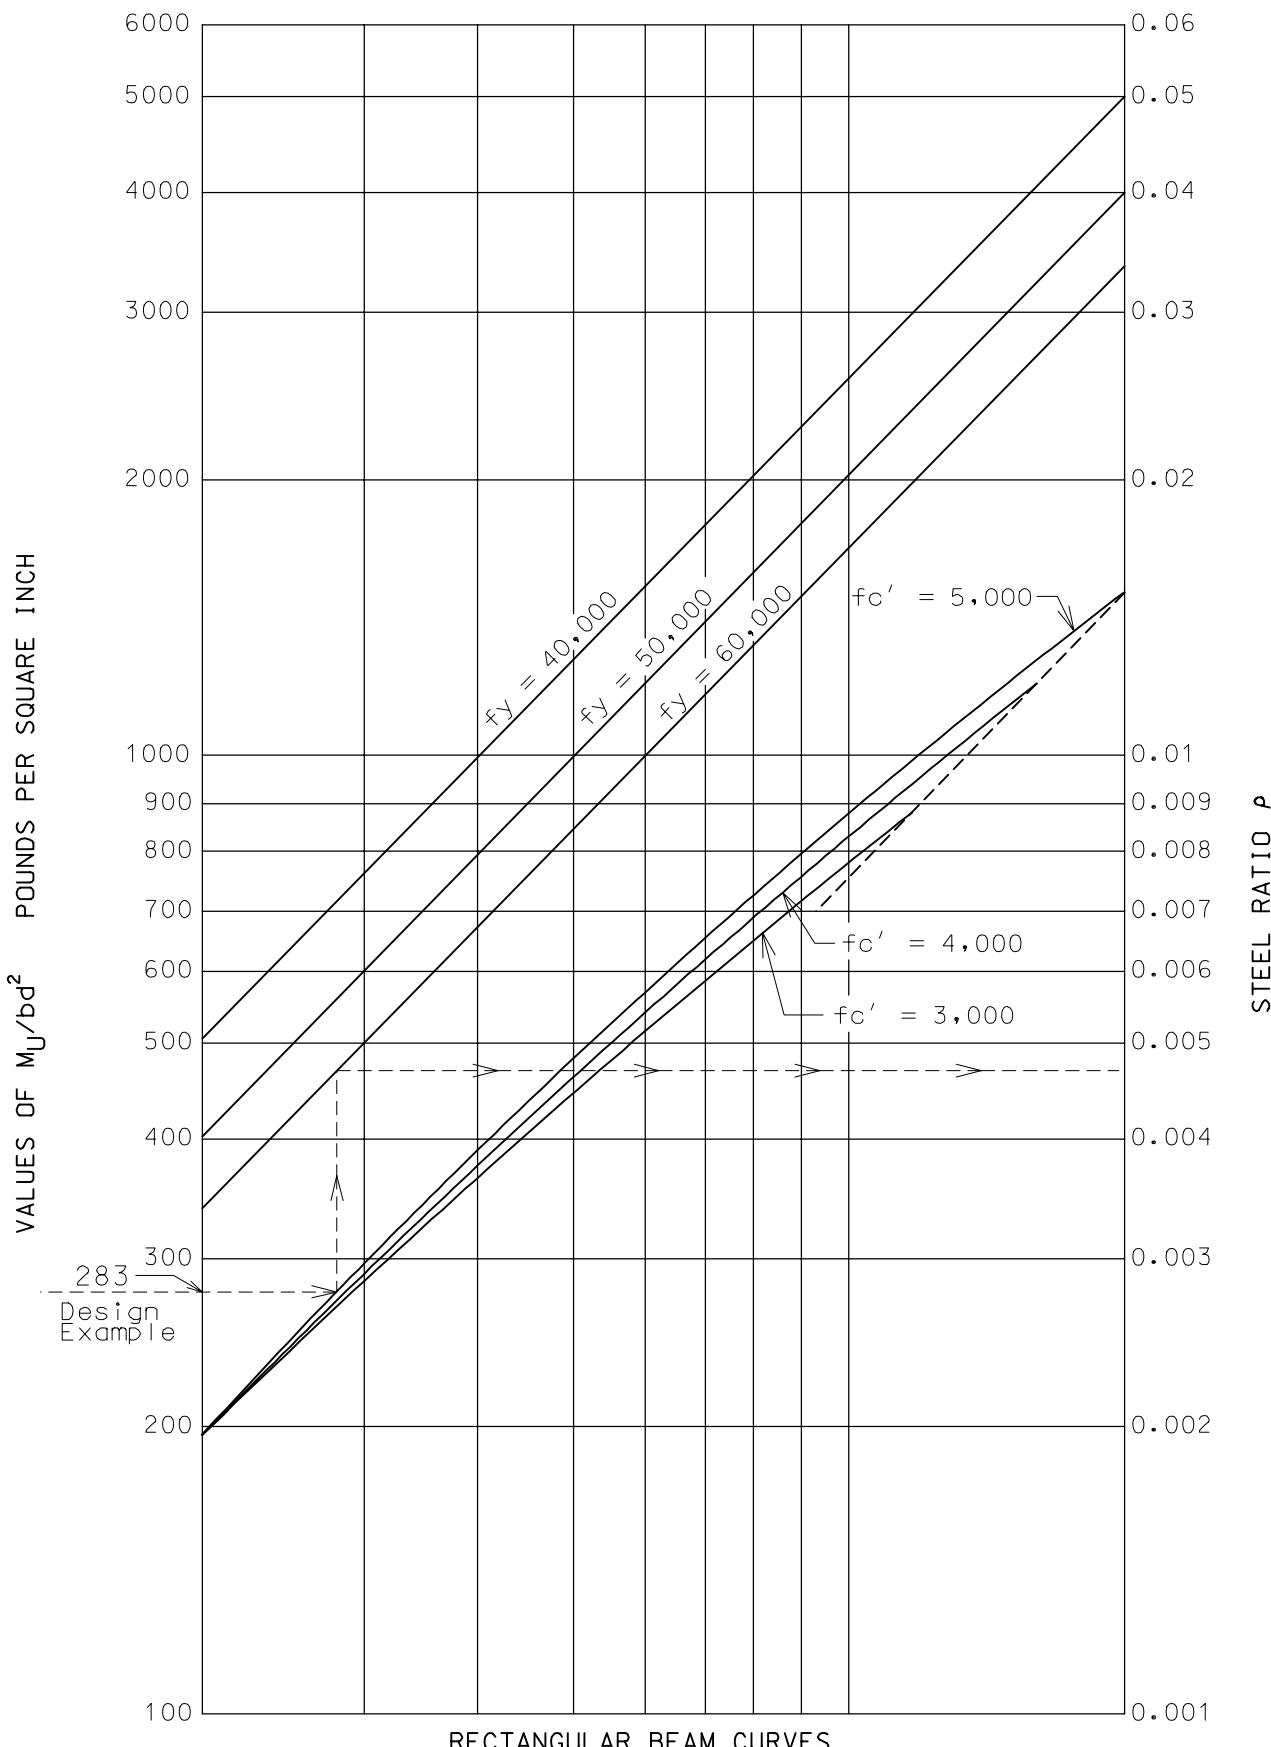

$$M_u = 47,083,230" LB = 3,924 \text{ ft.-kips.}$$

OK. M_u provided > required 3740 ft.-kips.

* See Computer Manual page BR200-3 for additional check.

SECTION PROPERTIES - STAND ARRANGEMENT & PROJECTION

The properties and strand arrangement of the most commonly used girders are shown on the following pages.

Other strand arrangements are permissible. If a web thickness greater than that shown on page 1.1-1B is required by design, consult Structural Project Manager.

* Varies

** #5 bars typical at each layer of bent-up strands.

(1) #5-strand tie bars normal of girder.

Notations used on the following pages are shown below:

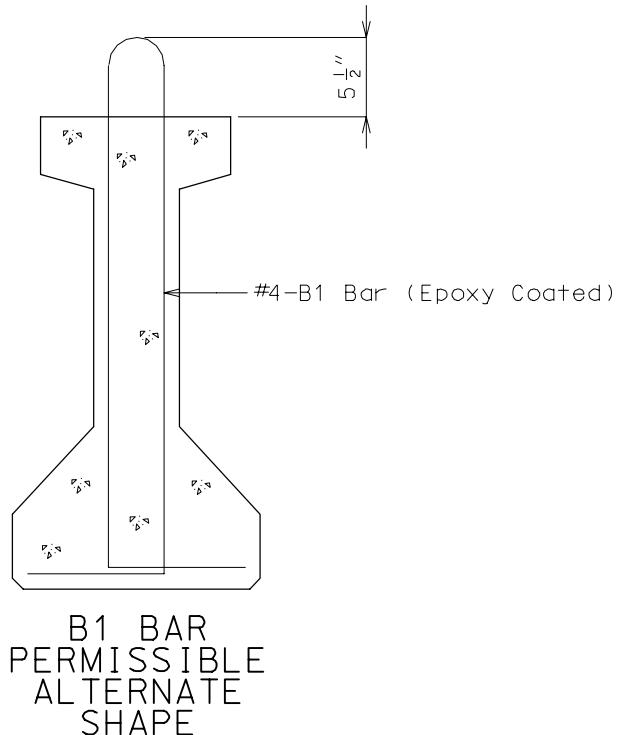

A = Cross-sectional area of girder.

y_s = Distance from centroid to bottom of girder.

I = Moment of inertia of girder.

Criteria used in finding maximum span lengths:

- 1.) Three equal spans
- 2.) Low-Relaxation, one-half inch diameter strands
- 3.) Only standard strand arrangement
- 4.) Class A1 Concrete with $f'c = 6000$ psi and $f'ci = 4500$ psi
- 5.) Minimum web thickness and flange width
- 6.) 16 inch barrier curb
- 7.) #6 Longitudinal temperature reinforcement (max.) with #8 @ 5" cts. Maximum negative moment reinforcement (maximum allowed configuration).
- 8.) Effective flange widths for type 7 girders (bulb-tees) used to determine maximum lengths are based on AASHTO 9.8.3.
- 9.) Maximum shear reinforcement in girder web is #5 @ 5" cts.
- 10.) Pre-Cast Panel Slab

GIRDER DESIGN (CONT.)

Design

NEGATIVE MOMENT BAR CUT-OFF: (WORKING STRESS CONTROLLING)

Area of slab bars required and stress in the slab bars are printed in program BR200.

Determine stress of the area of slab bars input into program at a point where the area required is larger than that input.

Interpolate along a straight line to where the stress is 24,000 psi.

Example:

60' Span, 8" Bearing Pad
 Distance Cl. to Cl. of Bearing = 58'-7"
 Area slab bars input = 1.80 in.²

Pt.	Area Slab Bars	Stress Slab Bars
0.9	1.80	-5,408.1
1.0	10.55	-23,693.1

(Cl. Brg.)

$$\text{Stress in } 1.80 \text{ in.}^2 \text{ of bars at 1.0} = \frac{(23,693.1) (10.55)}{1.80}$$

$$= (138,867.9) \text{ psi}$$

Pt. at which stress in 1.80 in.² of bars is equal to 24,000 psi =

$$0.9 + \frac{(24,000 - 5,408.1)}{(138,867.9 - 5,408.1) (10)} = 0.914 \text{ of } \& \text{ Brg. to } \& \text{ Brg.}$$

Span Length

Theoretical Cut-off Length from Cl. Bent:

$$60' - [(0.914) (58.58') + 0.42' + 0.29'] = 5.75'$$

Actual Cut-off Length of Cl. Bent:

$$\left. \begin{array}{l} 5.75' + \text{Development Length} \\ \text{or} \\ 1/10 \text{ of the span} \\ \text{or} \\ 8' \end{array} \right\} \text{Use Largest}$$

Note: Negative momentbar computations use a cracked section analysis to determine stresses.

GIRDER DESIGN (CONT.)

Design

NEGATIVE MOMENT BAR CUT-OFF (ULTIMATE STRENGTH CONTROLLING)

Example (Span 1 Length = 58'-0"):

Girder Type 6, $f'c(girder) = 5 \text{ ksi}$,
 Bearing Pad Length = 8", Distance ℓ to ℓ of Bearing = 56'-7",
 b = width of bottom flange of girder = 24",
 Load Factor Design, \emptyset = strength reduction factor = 1.0 for P/S member

Slab reinforcing steel $fy = 60 \text{ ksi}$,
 A_s = Area of slab bars in effective flange for cut-off point
 $A_s = 1.84 \text{ sq.in.}$ (by BR200 input)
 d = effective depth = distance from compression face of concrete to
 centroid of tension steel
 $d = 59.6875"$

$$C = \text{compression force} = 0.85(f'c)(b)(a)$$

$$T = \text{tension force} = (A_s)(f_y)$$

$$T = (1.84 \text{ sq.in.})(60 \text{ ksi}) = 110.4 \text{ kips}$$

Equating $C = T$ gives

$$a = \frac{T}{(0.85)(f'c)(b)}$$

$$a = \frac{110.4 \text{ kips}}{(0.85)(5 \text{ ksi})(24")} = 1.0824"$$

Strength $M_u = \emptyset T(d-a/2)$

$$\text{Strength } M_u = (1.0)(110.4 \text{ kips})(59.6875" - 1.0824"/2)/12 = 544.15 \text{ kip-ft}$$

Negative Moment due to (LL+I), live load plus impact, for truck load and lane load, and DL2 Moment with FWS(future wearing surface) at each tenth point (ℓ to ℓ of Bearing) are printed in the BR200 program.

DL2 = total composite uniform Dead Load
 In this example $DL2(w/FWS) = DL(SBC) + DL(FWS)$.
 $DL(SBC)$ = weight of safety barrier curb = 170 lb/ft (for each girder)
 $DL(FWS)$ = weight of future wearing surface = 228 lb/ft (for each girder)
 $DL2(w/FWS) = 170+228 = 398 \text{ lb/ft}$
 $DL2(w/o FWS) = (DL2 w/FWS)(170/398) = 0.4217(DL2 w/FWS)$

GIRDER DESIGN (CONT.)

Design

NEGATIVE MOMENT BAR CUT-OFF: (ULTIMATE STRENGTH CONTROLLING)

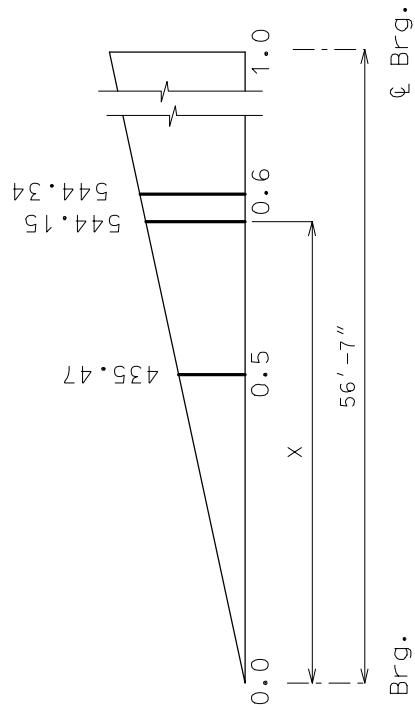

Example (Span 1) (Continued):

TABLE 1.1-11

Span 1 Girder Point	Load from BR200 Program			LF Load Mu = 2.17 (LL+I) + 1.3 DL2		
	Neg. (LL+I) Moment Truck Lane	DL2 Moment W/FWS	DL2 Moment W/O FWS(*)	Truck Load DL2 (W/O FWS)	Truck Load DL2 (W/FWS)	Lane Load DL2 (W/O FWS)
0.0	0.00	0.00	0.00	0.00	0.00	0.00
0.1	-43.56	-34.92	39.47	16.86	-43.21	-72.61
0.2	-87.11	-69.85	65.88	28.14	-103.38	-152.45
0.3	-130.65	-104.76	79.22	33.84	-180.52	-239.52
0.4	-174.21	-139.67	79.50	33.96	-274.69	-333.89
0.5	-217.75	-174.58	66.72	28.50	-385.78	-435.47
0.6	-261.31	-209.51	40.88	17.46	-513.90	-544.34
0.7	-304.85	-244.42	1.97	0.84	-658.96	-660.43
0.8	-348.40	-279.36	-50.00	-21.36	-821.03	-783.79
0.9	-391.96	-354.07	-115.04	-49.14	-1000.11	-914.43
1.0	-435.52	-517.03	-193.13	-82.49	-1196.15	-1052.32

All moments in Table are in kip-ft.

(*) See page 1.1-10 for calculation.

Interpolate the worst case above along a straight line to determine the point at which the moment above is equal to Strength Mu of 544.15 kip-ft.

$$\frac{X - 0.5}{0.6 - 0.5} = \frac{(-544.15) - (-435.47)}{(-544.34) - (-435.47)}$$

$$X = 0.5998 \text{ (of } \ell \text{ to } \ell \text{ brg. span length)}$$

Theoretical cut-off length = $(1.0 - 0.5998)(56.5833') + 0.4167' + 0.2917' = 23.3516'$

Actual cut-off length = $23.35' + \text{Development Length}$
 Or $8\frac{1}{10}'$ (span) = $\frac{8}{10}(58') = 5.80'$
 Or $8\frac{1}{10}''$ minimum

ℓ Brg.

ℓ Brg.

GIRDER DESIGN (CONT.)

Design

MINIMUM PRESTRESSING STRANDS:

The following instructions are provided for checking the required minimum prestressing strands for Prestressed Girders.

Standard Girders except Bulb Tee Girders designed by the BR200 Prestress Computer Program do not require the checking of minimum strands. When a strand selection is forced to other than a standard strand arrangement as shown in the Bridge Manual, additional checks are required.

All Girders are considered to meet the minimum prestressing strand requirements of AASHTO 9.18.2 when MU provided is greater than 1.33 times MU required.

The Formula needed to make a check of minimum strands with an example application follows:

CRACKING STRESS:

$$f_{MR} = 7.5 \sqrt{f'c}$$

$$f_{ACT} = \frac{P}{A_N} + \frac{PeY_B}{I_N} - \frac{M_{DL1} Y_B}{I_N}$$

$$f_{ACT} + f_{MR} = \frac{M_{MR} Y_{BC}}{I_C}$$

$$M_{MR} = \frac{I_C}{Y_{BC}} (f_{ACT} + f_{MR})$$

$$1.2 (M_{MR} + M_{DL1}) < M_{PROV}$$

f_{ACT} = Stress due to P/S and DL1 (psi)

f_{MR} = Modulus of rupture (psi)

$f'c$ = Compressive strength of concrete at 28 days (psi)

P = Prestress force (after losses) causing compression in bottom fiber (lbs.)

e = Eccentricity of strands from N.A. (in.)

Y_B = Non-composite distance to gravity center from extreme bottom fiber (in.)

Y_{BC} = Composite distance to gravity center from extreme bottom fiber (in.)

A_N = Non-composite area (sq. in.)

I_N = Non-composite moment of inertia (in.⁴)

GIRDER DESIGN (CONT.)

Design

CRACKING STRESS (CONT.):

 I_c = Composite moment of inertia (in.⁴) M_{DLI} = Moment service load dead load I (in.-lbs.) M_{MR} = Moment required to increase actual stress in compression to cracking stress in tension. M_{UPROV} = Ultimate moment provided from BR200. M_{UREQ} = Ultimate moment required from BR200.

Example - Minimum Strand:

$$f_{MR} = 7.5 \sqrt{5,000} \quad M_u \text{ Required} = 1,176 \text{ (kips-ft.)}$$

$$f_{MR} = 530 \text{ psi} \quad M_u \text{ Provided} = 1,640 \text{ (kips-ft.)}$$

$$f_{ACT} = \frac{213,453}{644.1} + \frac{213,453 \times 23.89 \times 25.89}{236,105} - \frac{314,908 \times 12 \times 25.89}{236,105}$$

$$f_{ACT} = 331 + 559 - 414$$

$$f_{ACT} = 476 \text{ psi}$$

$$f_{ACT} + f_{MR} = 476 + 530 = 1,006$$

$$M_{MR} = \frac{592,854 (1,006)}{42.6 (12,000)}$$

$$M_{MR} = 1,166.7 \text{ (kips-ft.)}$$

$$1.2 (M_{MR} + M_{DLI}) = 1.2 (1,166.7 + 314.9) \\ = 1,777.9 > 1,640$$

MU_{PROV} AASHTO 9.18.1

Eight strands does not satisfy AASHTO 9.18.2 however,

Mu Provided > 1.33 (Mu Required)

1,640^(kips-ft.) > 1,564^(kips-ft.)

Eight strands O.K

GIRDER DESIGN (CONT.)

Design

DRAPE STRANDS:

Draped strands, although they add to the shear strength of the girder, are primarily used to keep the girder stresses at the end, both top and bottom, within allowable limits while developing the full capacity of the girder and slab at midspan.

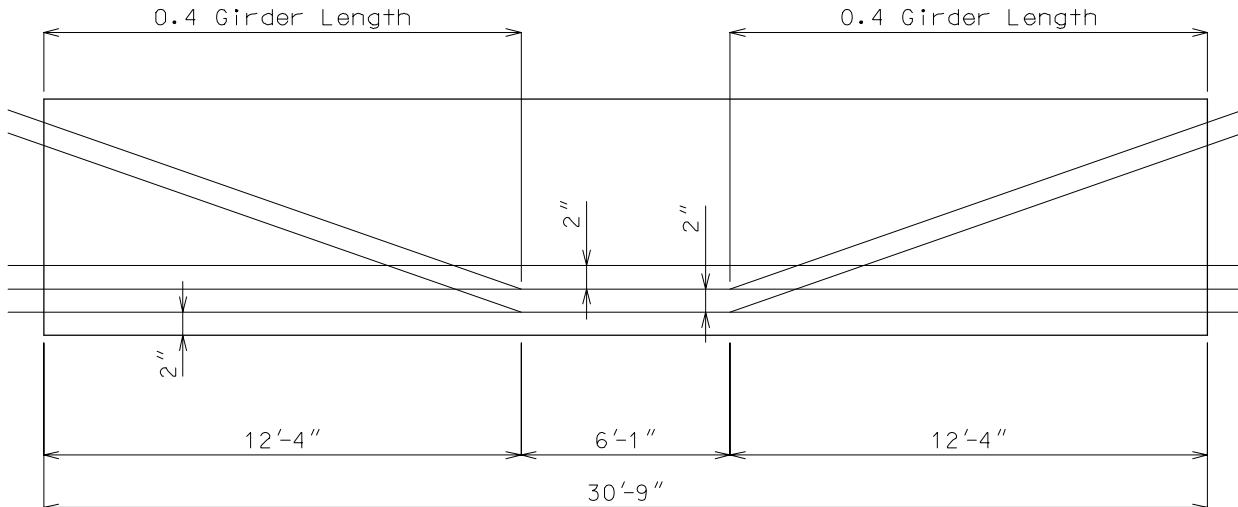

The draped strands should be held down at points 0.4 of the distance from each end of the girder.

STRAND FAILURE:

Jacking force applied to prestress strands produces an excessive vertical uplift in short spans on tall girders resulting in failure of draped strand tie downs.

Short spans less than 40 feet are to use straight strands for all girders greater 2'-8" tall. Use at least two straight strands at the top of the girder when straight strands are used. Where straight strands will not work a single hold down point may be used.

Investigate the possibility of using all straight strands when strength check of a hold-down device exceeds allowable (See this section page 1.1-15).

TYPICAL DRAPE STRAND LAYOUT WITH FAILURE

Strands are normally 1/2" Dia. (0.153 sq. in.) low relaxation strands grade 270.

Note: Strand distance to full development length = 8'-5".
(Based on FHWA recommendation.)

GIRDER DESIGN (CONT.)

Design

HOLD-DOWN DESIGN CHECK

Prestress girders with draped strands require strength checks of hold-down devices not to exceed allowable limits.

An example of the strength check of a hold-down device for a 4'-6" girder with three rows of two strands draped is as follows:

The maximum capacity for the hold-down is a total of 42 kips. The maximum capacity per strand is 5 kips with 10 kips maximum for a two strand row due to bolt shear.

Check 4'-6" Girder Type 6
Seq. 143 18-strands 6 draped

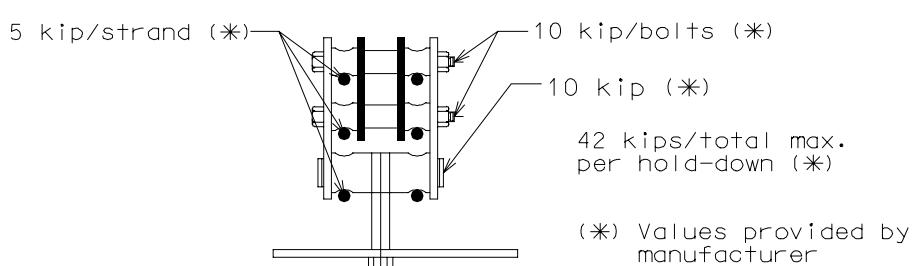

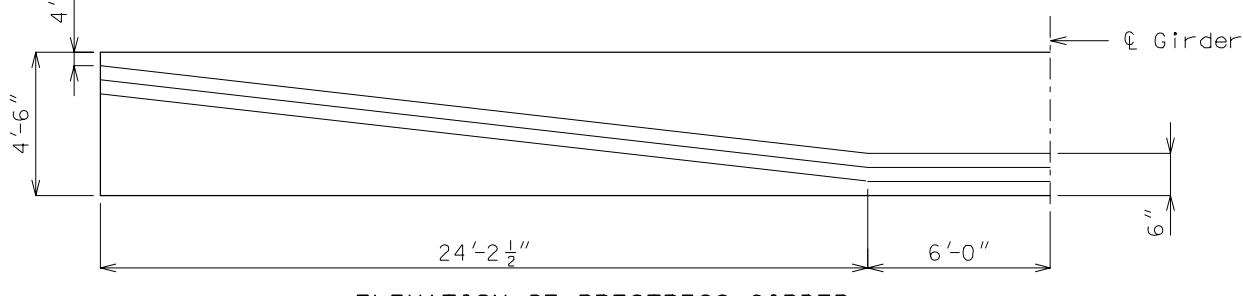

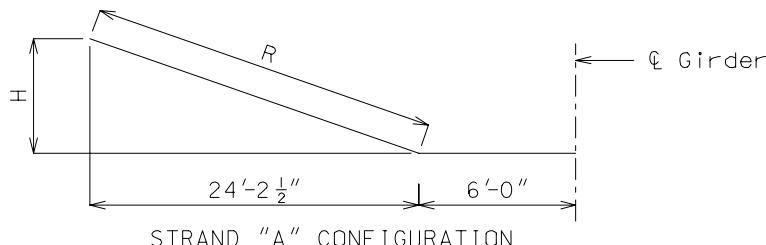

Compute "H"
4'-6" = 54"

-4" to top draped strands at end
-6" to top draped strands at hold down
H = 44" = 3.67 ft.

Compute "R"

$$R = \sqrt{3.67^2 + 24.21^2}$$

$$R = 24.49 \text{ ft.}$$

HOLD-DOWN DEVICE

$$\text{Uplift force per strand} = (\text{strand force}) \times (H/R)$$

Girder length = 60.42 ft.

Check: 31 kip/strand force

$$31 \times 3.67/24.49 = 4.65 \text{ kip/strand} < 5 \text{ kips, OK uplift/strand less than allow.}$$

9.3 kips/bolt < 10 kips, OK uplift/bolt less than allow.

$$6 (4.65) = 27.9K < 42K, OK uplift/hold-down less than allow.$$

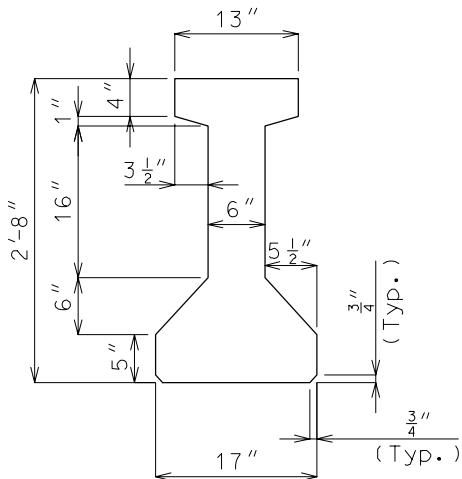

If necessary lower draped strand end location to meet criteria or use straight strands. (Applicable to both I-Girders and Double-Tee Girders).

Note: A single point tie down has twice the uplift force.

Bridge Manual

Prestressed Concrete I-Girders - Section 3.55

Page: 1.10-1

MATERIALS

Design

Concrete:

Prestressed Members = Class A1

$$f'c = 5000 \text{ psi} \quad f'c = 6000 \text{ psi} \quad n = 6 \text{ (Strength)}$$

$$f'ci = 4000 \text{ psi} \quad f'ci = 4500 \text{ psi} \quad n = 8 \text{ (Deflection)}$$

(For notations, refer to current AASHTO Specifications).

Deck Slab = Class B2

$$f'c = 4000 \text{ psi} \quad n = 8$$

Reinforcing Steel:

Mild Steel

$$\begin{array}{ll} fy = 60,000 \text{ psi} & (\text{Refer to Missouri Standard}) \\ fs = 24,000 \text{ psi} & \text{Specifications) } \end{array}$$

Prestress Steel

Refer to AASHTO M203 (ASTM A416) Grade 270 (*) for uncoated seven-wire low relaxation strands, with exceptions as shown in the table below:

Nominal Diameter of Strands	inch	0.5
Nominal Area of Strands	sq. in.	0.1530
Minimum Ultimate Strength	lbs.	41,300
Maximum Prestress	lbs.	31,000

(*) Grade 270 Which refers to the average ultimate strength = 270 ksi

The maximum prestress in the table represents about 75% of the ultimate strength.

The size of the strands to be used will be limited to $\frac{1}{2}$ " diameter. Strands will be draped where practical.

Note: Use of higher strength concrete ($f'c = 6,000 \text{ psi}$) or larger strand size may be required in unusual situations. Consult Structural Project Manager.

ALLOWABLE CONCRETE STRESSES

Design

The following criteria is shown for clarity and is in accordance with AASHTO 9.15.

$$f'c = 5,000 \text{ psi}, f'ci = 4,000 \text{ psi}$$

- A. Temporary stresses before losses except as noted:

Compression $0.6 f'ci = 0.6 \times 4,000 \text{ psi} = 2448 \text{ psi } (*)$

Tension

Precompressed tensile zone
No temporary allowable stresses are specified.
See paragraph "B" below.

In tension areas with no bonded reinforcement..... $3\sqrt{f'ci} = 3\sqrt{4,000} = 190 \text{ psi}$

Where the calculated tensile stress exceeds this value, bonded reinforcement shall be provided to resist the total tension force in the concrete computed on the assumption of an uncracked section. The maximum tensile stress shall not exceed...

$$7.5\sqrt{f'ci} = 7.5\sqrt{4,000} = 475 \text{ psi}$$

- B. Stresses at service loads after losses:

Compression..... $0.4 f'c = 0.4 \times 5,000 = 2,000 \text{ psi}$

Tension in the precompressed tensile zone

(a) For members with bonded reinf. (**) .. $6\sqrt{f'c} = 6\sqrt{5000} = 425 \text{ psi}$

(b) For members without bonded reinf.....= Zero

Tension in other areas

Tension in other area is limited by the allowable temporary stresses specified in "A" above

- C. Cracking stress:

Modulus of rupture from tests or (for normal weight concrete) ..

$$\dots\dots\dots 7.5\sqrt{f'c} = 7.5\sqrt{5,000} = 530 \text{ psi}$$

- D. Negative moment stresses in girders made continuous after deadload of slab is in place:

Tension in negative moment reinforcement..... $f_y = 60,000 \text{ psi}$
 $f_s = 24,000 \text{ psi}$

Compression in concrete at bottom of girder
 (See paragraph no. 2, page 1.1-3 this section
 and AASHTO 9.7.2)..... $f'c = 5,000 \text{ psi}$
 $f_c = 0.6f'c$

(*) BR200 allows 2% overstress

(**) Strands qualify if not debonded at ends.

PRESTRESS LOSS (LOW RELAXATION)
AASHTO 9.16.2

Design

$f_s = 270,000$ psi, Grade 270 low relaxation strands
 $f'_c = 5,000$ psi
 $f'_{ci} = 4,000$ psi

$$\left[\frac{(SH) + (ES) + (CR_C) + (CR_S)}{fs_i} \right]$$

$$\left[\frac{6000 + \frac{Es}{Ec_i} fc + 8.5 fc + (5000 - 0.1 Es - 0.05(SH + CR_C))}{fs_i} \right]$$

$$\text{Reduce to : } \frac{10,700 + (0.9 \left(\frac{Es}{Ec_i} \right) + 8.08) fc}{fs_i}$$

SH = Shrinkage
 ES = Elastic Strain
 $CR_C = \text{Concrete Creep}$
 $CR_S = \text{Steel Creep}$

$CR_C = 12 fcir - 7 fcds$

$CR_C = 12 fc - 7/2 fc = 8.5fc \text{ (Approximate Estimate)}$

$Ec_i = 150^{1.5} 33 \sqrt{f'_{ci}}, \quad ES = \frac{Es}{Ec_i} fcir = \frac{Es}{Ec_i} fc \text{ (Approximate Estimate)}$

$fcir$ = Concrete stress at centroid of P/S steel at point considered due to P/S and dead load at release.

fc = $fcir$ (Assume $fcir = fc$)

$fc = 0.4(4,000) = 1,600$ psi (Estimate average)

$fcds$ = Concrete stress at centroid of P/S Steel (due to dead load)
 (Assume $fcds = 1/2 fc$)

fs_i = Initial stress in P/S steel

$fs_i = 270,000 \text{ psi} \times 75\% = 202,500 \text{ psi}$

$Ec_i = 150^{1.5} 33 \sqrt{4,000} = 3,834,253.5 \text{ psi}$

$Es = 28,000,000 \text{ psi (AASHTO 9.16.2.1.)}$

$\frac{Es}{Ec_i} = 7.30$

$\frac{10,700 + (0.9 \times 7.30 + 8.08) 1600}{202,500} = 16.9\% \text{ (Total loss)}$

$202.5 \text{ ksi} \times 16.9\% = 34.22 \text{ ksi}$

Total loss due to all causes, except friction, is 34.22 ksi.

(Friction losses are applied to post-tensioned girder only.)

Use 8.84% for initial loss and 8.84% for final loss for design.

$202.5 \text{ ksi} \times 8.84\% = 17.90 \text{ ksi} = \text{initial loss}$

$202.5 - 17.90 = 184.60 \text{ ksi}$

$184.60 \text{ ksi} \times 8.84\% = 16.32 \text{ ksi} = \text{final loss}$

$17.90 + 16.32 = 34.22 \text{ ksi} \approx 34.22 \text{ ksi} \times 16.9\% = \text{total loss}$

In the above design example, if tension exceeds AASHTO Specifications, (425 psi for 5,000 psi concrete) the girder will have to be modified to limit stress to 425 psi.

PRESTRESS LOSS (LOW RELAXATION) (CONT.)

Design

$$f'c = 6,000 \text{ psi}$$

$$f'ci = 4,500 \text{ psi}$$

Grade 270 low relaxation strands

$$fc = 0.4(4,500) = 1,800 \text{ psi (Estimated average)}$$

$$Ec_i = 150^{1.5} \cdot 33 \sqrt{f'ci} = 4,066.840 \text{ psi}$$

$$\frac{Es}{Ec} = \frac{28,000,000}{4,066,840} = 6.89$$

AASHTO 9.16.2.1.3: $CR_c = 12fc - 7/2fc = 8.5fc$ (approximate estimate)

$$\boxed{\frac{(SH)}{6,000} + \frac{(ES)}{\frac{Es}{Ec_i}} fc + 8.5f_c + (5,000 - \frac{(CR_s)}{0.1Es} - 0.05(SH + CR_c))}$$

Reduce to: $\frac{10,700 + (0.9(\frac{Es}{Ec_i}) + 8.08)fc}{fsi}$

$$fc = 0.4(4,500) = 1,800 \text{ psi (estimated average)}$$

$$\frac{Es}{Ec_i} = 6.89$$

fsi = Initial stress in low relaxation strands stressed to 75% of ultimate (*)

$$fsi = 270,000 \text{ psi} \times 75\% = 202,500 \text{ psi}$$

$$\frac{10,700 + (0.9 \times 6.89 + 8.08) \times 1800}{202,500} = 18.0\%$$

$202.50 \text{ ksi} \times 18.0\% = 36.45 \text{ ksi} = \text{total loss except friction}$
 Use 9.44% for initial loss and 9.44% for final loss.

$$202.50 \text{ ksi} \times 9.44\% = 19.12 \text{ ksi} = \text{initial loss}$$

$$202.5 - 19.12 = 183.38 \text{ ksi}$$

$$183.38 \text{ ksi} \times 9.44\% = 17.31 \text{ ksi} = \text{final loss}$$

$$19.12 + 17.31 = 36.43 \text{ ksi} \approx 36.45 \text{ ksi} = 202.5 \text{ ksi} \times 18.0\% = \text{total loss}$$

$$\text{P/s force initial} = (183.38 \text{ ksi})(0.153 \text{ in.}^2/\text{strands})(\text{no. of strands})$$

$$\text{P/s force final} = ((202.5 - 36.43) \text{ ksi})(0.153 \text{ in.}^2/\text{strand})(\text{no. of strands})$$

(*) Suggested by FHWA: when using 3/8" Ø strands, max. fsi = $0.7 \times 250 \text{ ksi}$ or $0.7 \times \text{ultimate stress}$, whichever is smaller. Larger initial stresses will cause debonding.

camber due strands, beam weight and 28 day creep (inch),
camber L/4 due strands, beam weight and 28 day creep (inch),
deflection due to slab weight (inch),
camber centerline due strands, beam weight, 28 day creep,
slab and diaphragm (inch), and
camber quarterpoint due strands, beam weight, 28 day
creep, slab and diaphragm (inch).

PRESTRESS CAMBER (CONT.)

Design

Formulas used:

Positive deflect up Negative deflect down 

$$\Delta_1 = 144 \times 10^3 \times \left[\frac{F_{01}(e_1)(L^2)}{8E_i I} + \frac{F_{02}(e_2+e_3)}{E_i I} \left(\frac{L^2}{8} - \frac{a^2}{6} \right) - \frac{F_{02}(e_3)(L^2)}{8E_i I} \right] \\ (a = [L - (\text{ft to ft tie downs})] \div 2) \text{ ft.}$$

Beam weight camber

$$\Delta_2 = \frac{5W_B(L^4)}{384E_i I} (1728 \times 10^3)$$

Slab weight camber

$$\Delta_s = \left[\frac{5W_S(L^4)}{384E_f I_{TR}} + \frac{P(L^3)}{48E_f I_{TR}} + \frac{2PsX(3L^2 - 4X^2)}{48E_f I_{TR}} \right] (1728 \times 10^3)$$

Force straight strands (1/2" low relaxation strands)

$$F_{01} = (\text{no. of straight strands}) \times [31.0 - (17.1 \times 0.153)] \text{ kips}$$

Force draped strands ($\frac{1}{2}$ " low relaxation strands)

$$F_{02} = (\text{no. of draped strands}) \times [31.0 - (17.1 \times 0.153)] \text{ kips}$$

$$270 \text{ ksi} \times 75\% \times (0.153 \text{ sq. in.}) = 31 \text{ kips per strand}$$

$$202.5 \times (1 - 0.0884) = 184.6 \text{ ksi}$$

$$184.6 \times (1 - 0.0884) = 168.28 \text{ ksi}$$

$$202.5 - 168.28 = 34.22 \text{ ksi} = \text{Total loss}$$

$$\text{Average loss} = \text{Total loss}/2 = 34.22/2 = 17.1 \text{ ksi}$$

e_1 = dist. centroid beam to centroid straight strand (in.)

e_2 = dist. centroid beam to low centroid draped at center of beam (in.)

e_3 = dist. centroid beam to up centroid draped at end of beam (in.)

L = length (ft.) (ft bearing to ft bearing).

I = moment of inertia (in.⁴) non-transformed.

I_{TR} = moment of inertia (in.⁴) transformed.

Ps = concentrated loads due to variable slab thickness on each end.

X = dist. from ft brg. to Ps .

P = concentrated load due to diaphragm at center of span (kips)

W_B = uniform beam load (kips/ft.)

W_S = uniform slab load (kips/ft.)

F = factor for 28 day creep

E_i = modulus of elasticity corresponding to initial girder concrete strength

E_f = modulus of elasticity corresponding to final girder concrete strength

$$\Delta_c = F(\Delta_1 - \Delta_2) - \Delta_s$$

$$\Delta @ 0.10 = 0.314 \quad (\Delta @ c)$$

$$\Delta @ 0.20 = 0.593 \quad (\Delta @ c)$$

$$\Delta @ 0.25 = 0.7125 \quad (\Delta @ c)$$

$$\Delta @ 0.30 = 0.813 \quad (\Delta @ c)$$

$$\Delta @ 0.40 = 0.952 \quad (\Delta @ c)$$

Note: Compute and show on plans camber at $\frac{1}{4}$ points for bridges with spans less than 75', 1/10 points for spans 75' and over.

SUPERSTRUCTURE DESIGN

Design

Live Load Distribution:

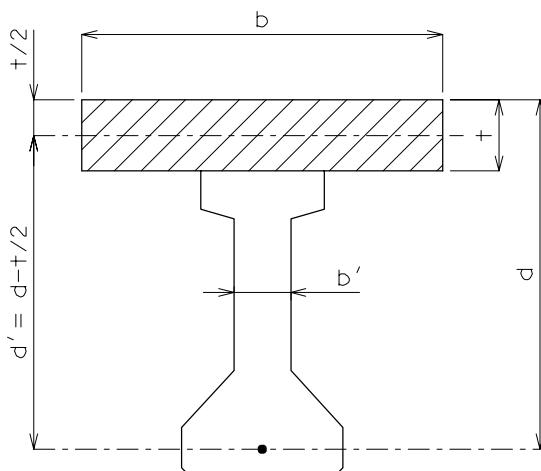

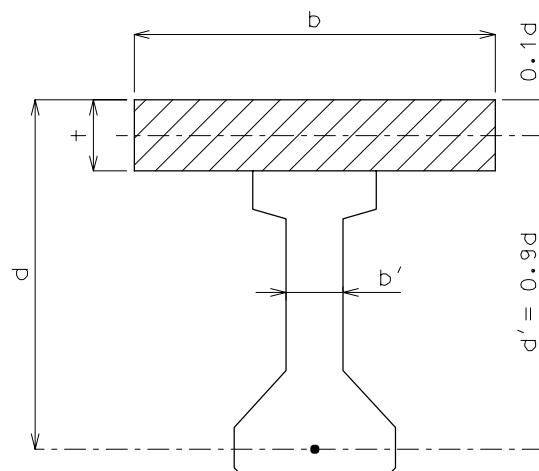

The live load distribution to girders may be assumed to be the same as the AASHTO distribution for concrete floors on steel I-Beam stringers. These factors may be found in section 1.3.

Ultimate Load Capacity:

The ultimate load capacity shall be not less than 1.3 times (the weight of the girder plus the weight of the slab and diaphragms plus the weight of the future wearing surface) plus 2.17 times the design live load plus impact.

Ultimate Strength:

The ultimate moment on a prestressed girder as determined in accordance with the ultimate load capacity indicated above, shall not be greater than the ultimate strength determined as follows:

Where $t \leq 0.2d$ Where $t > 0.2d$ 

$$\left. \begin{aligned} M_u &= A_s f'_s (d-t/2) \\ &\text{or} \\ M_u &= 0.85 f'_c b t (d-t/2) \end{aligned} \right\}$$

Use the lesser
in each case

$$\left. \begin{aligned} M_u &= A_s f'_s (0.9d) \\ &\text{or} \\ M_u &= 0.85 f'_c b (0.2d) (0.9d) \end{aligned} \right\}$$

Where: A_s = Area of p/s strands in bottom flange
 b , b' , t and d = as shown above

f'_s = Ultimate strength of p/s strands

f'_c = Ultimate strength of slab concrete = 4,000 psi

Maximum Prestressing Steel Area:

$$A_s = \frac{0.85 f'_c b t}{f'_s} \quad \text{When } t \leq 0.2d$$

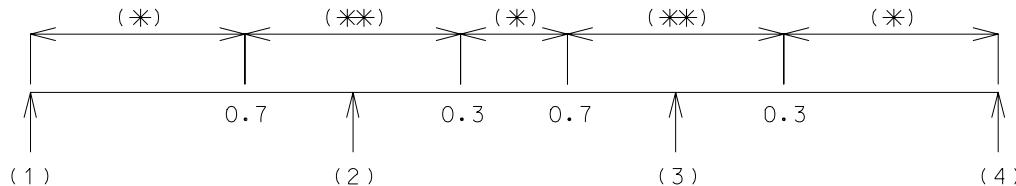

$$A_s = \frac{0.85 f'_c b (0.2d)}{f'_s} \quad \text{When } t > 0.2d$$

In lieu of the above, AASHTO - Article 9.17 & 9.18 may be used.
 (This is the method used by computer program BR200)

WEB REINFORCEMENT

Design

(5" Min. - 21" Max. bar spacing for #4 bars)
 (5" Min. - 24" Max. bar spacing for #5 bars)

(*) Prestressed concrete members shall be reinforced for diagonal tension stresses. Shear reinforcement shall be placed perpendicular to the axis of the member. The formula to be used to compute areas of web reinforcement is as follows:

$$A_V = \frac{(V_U - V_C)s}{2f_{sy}jd}; \text{ where } V_C = (0.06f'_c)b'jd, \text{ but not more than } 180 b'jd.$$

But shall not be less than $A_V = \frac{100 b's}{60,000} = 0.00167 b's$.

(**) Since large moments and large shears occur in the same area of the girder near the interior supports, the AASHTO formula (AASHTO - 9.20 -Shear) for computing the area of web reinforcement has been modified. The formula to be used to compute areas of web reinforcement near interior supports is as follows:

$$A_V = \frac{(V_U - V_C)s}{f_{sy}jd}; \quad V_C = 180 b'jd.$$

The value "jd" is the distance from the slab reinforcement to the center-of-gravity of the compression area under ultimate loads.

Use #4 shear reinforcement when possible. Alternate B1 bar will not work with #5. (See page 1.1-6A)

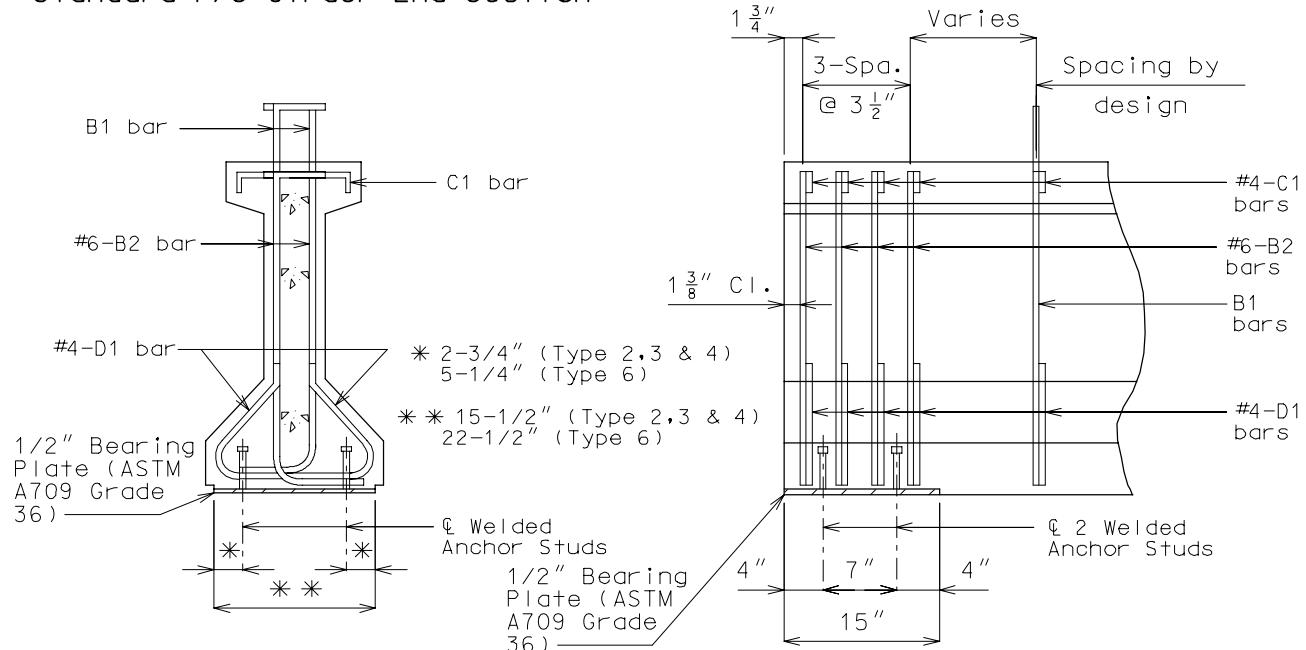

WEB REINFORCEMENT (CONT.)

Design

ANCHORAGE ZONE REINFORCEMENT - AASHTO Article 9.21.3

The following detail meets the criteria for anchorage zone reinforcement for pretensioned girders (AASHTO Article 9.21.3) for all MoDOT standard girder shapes.

Standard P/S Girder End Section

SOLE PLATE ANCHOR STUDS

The standard 1/2" sole plate will be anchored with four 1/2" x 4" studs.

Studs shall be designed to meet the criteria of AASHTO Div. I-A in Seismic Performance Category C or D.

Stud capacity is determined as follows:

$$\text{Stud Cap.} = (n)(As)(0.4Fy)(1.5)$$

where: n = no. of studs
 As = area of stud
 Fy = yield strength of stud (50 ksi)
 0.4Fy = Allowable Shear in Pins AASHTO Table 10.32.1A
 1.5 = seismic overload factor

If required, increase the number of 1/2" studs to six and space between open B2 bars. If this is still not adequate, 5/8" studs may be used. The following table may be used as a guide to upper limits of dead load reactions:

Seismic Bearing Plate Anchor Design

No. of Studs	Stud Dia.	Max. Allowable D.L. Reaction (Kips)	
		A = 0.30	A = 0.36
4	1/2"	78	65
6	1/2"	117	98
4	5/8"	122	102
6	5/8"	184	153

The minimum 3/16" fillet weld between the 1/2" bearing plate and 1-1/2" sole plate is adequate for all cases.

STRANDS - MISCELLANEOUS

Design

Detensioning

In all detensioning operations the prestressing forces must be kept symmetrical about the vertical axis of the member and must be applied in such a manner as to prevent any sudden or shock loading.

General Information

Splicing:

One approved splice per pretensioning strand will be permitted provided the splices are so positioned that none occur within a member. Strands which are being spliced shall have the same "Twist" or "Lay". Allowance shall be made for slippage of the splice in computing strand elongation.

Wire failure:

Failure of one wire in a seven wire pretensioning strand may be accepted, provided that, it is not more than two percent of the total area of the strands.

Sand Blasting:

On structures where it is questionable as to the clarity of areas to be sandblasted: show limits of sandblasted area in a plan view of details on girder ends (bent sheet). However, generally, sandblasting is covered by Missouri Standard Specification 705.4.14.

Bridge Manual

Prestressed Concrete I-Girders - Section 3.55

Page: 1.17-1

DIMENSIONAL TOLERANCES (*)

Note: The following dimensional tolerances will be required.

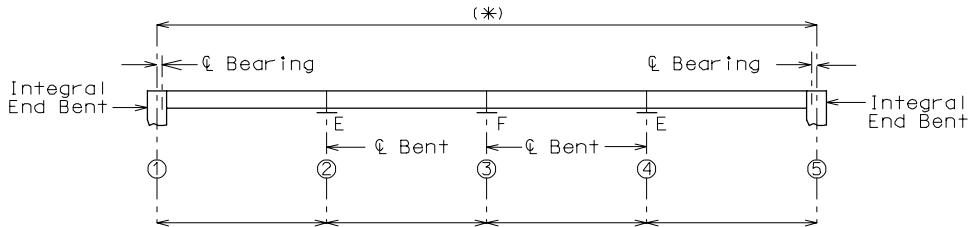

Design

Length of beam	$\pm 1/8$ inch per 10 feet of beam length, but not greater than $3/4$ inch
Width (flanges, web and fillets)	$+ 3/8$ inch, $- 1/4$ inch
Depth (flanges, web and fillets)	$\pm 1/4$ inch
Depth (overall)	$+ 1/2$ inch, $- 1/4$ inch
Horizontal alignment (deviation from a straight line parallel to centerline of member)	$1/2$ inch max., to 40 feet lengths $3/4$ inch max., 40 to 60 feet lengths 1 inch max., 60 feet or greater lengths
Camber (deviation from design camber within 7 days of strand release)	$\pm 1/2$ inch to 80 feet length, ± 1 inch greater than 80 feet length
Stirrup bars (projection above top of beam)	$\pm 3/4$ inch
Stirrup bars (longitudinal spacing)	± 2 inches
Tendon position	$\pm 1/4$ inch center of gravity of strand group and individual tendons
Position of deflection points for deflected strands	± 6 inches, longitudinal
Position of lifting devices	± 6 inches, longitudinal
Side inserts (centerline to centerline and centerline to end)	$\pm 1/2$ inch
Coil Inserts (Centerline to centerline and centerline to end)	± 2 inches horizontal, except must be 3 inches or more from end of beam and within reinforcement cage of bent, ± 1 inch vertical
Slab Drain Inserts	$\pm 1/2$ inch from designated location, engineer may approve location ± 6 inches from design, multiple inserts for single drain must be within $\pm 1/2$ inch of vertical line
Exposed beam ends (deviation from square or designated skew)	Horizontal $\pm 1/4$ inch, vertical $\pm 1/8$ inch per foot of beam height
Bearing area (deviation from plane)	$\pm 1/8$ inch
Bearing plates (centerline to centerline)	$\pm 1/8$ inch per 10 feet of beam length, but not greater than $3/4$ inch
Bearing plates (centerline to end of beam)	$\pm 1/2$ inch
Diaphragm Hole Location	$\pm 1-1/2$ inches for centerline of group $\pm 1/2$ inch within group

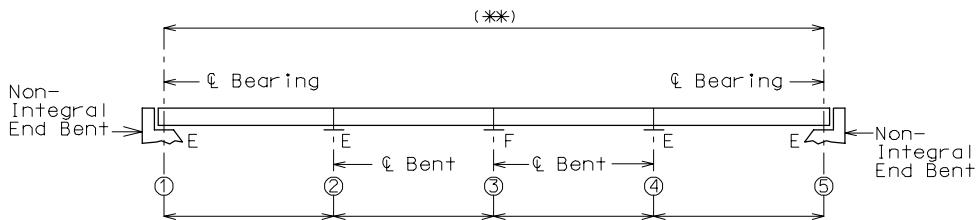

* Also see Section 705.5 of Missouri Standard Specifications.

STRUCTURE LENGTH

Length

(*) Maximum length from End Bent to End Bent = 600 feet.

TYPICAL CONTINUOUS PRESTRESS STRUCTURE
(INTEGRAL END BENTS)

(**) Maximum length from End Bent to End Bent = 800 feet.

TYPICAL CONTINUOUS PRESTRESS STRUCTURE
(NON-INTEGRAL END BENTS)

Haunching and Girder Steps

Haunching for a P/S I-Girder bridge is the distance between the top of the girder and the bottom of the slab.

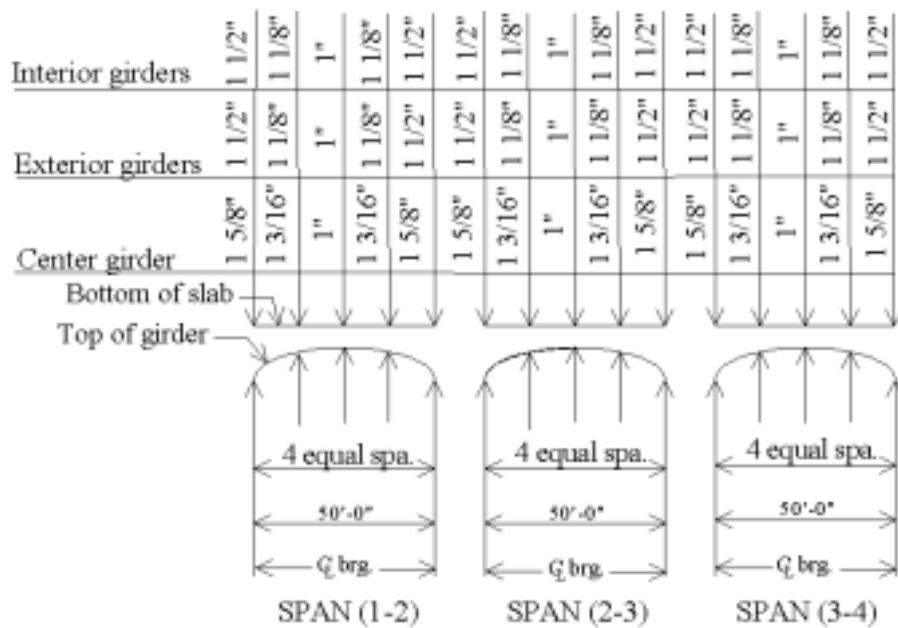

Haunching shall be computed at quarter (1/4) points for bridges with spans less than 75 feet, and at tenth (1/10) points for spans 75 feet and longer. A haunching diagram, as shown below, shall be provided on all P/S I-Girder bridges.

A minimum haunch of 1 inch at the centerline of girder and 1/2 inch at the edge of the girder shall be provided to allow for construction tolerances and normal concrete variations.

A maximum haunch at the centerline of the girder of 2-1/2 inches is allowed when prestressed panels are used, and 3-1/2 inches when only the cast in place option is used. (The maximum joint filler thickness supporting panels is 2"; the remaining haunch thickness will be addressed by varying the slab thickness)

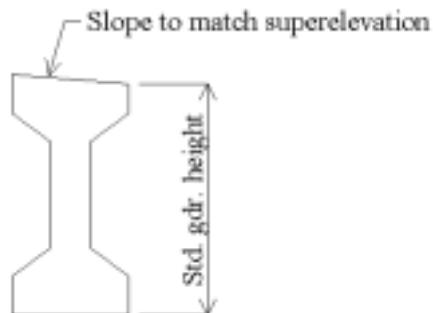

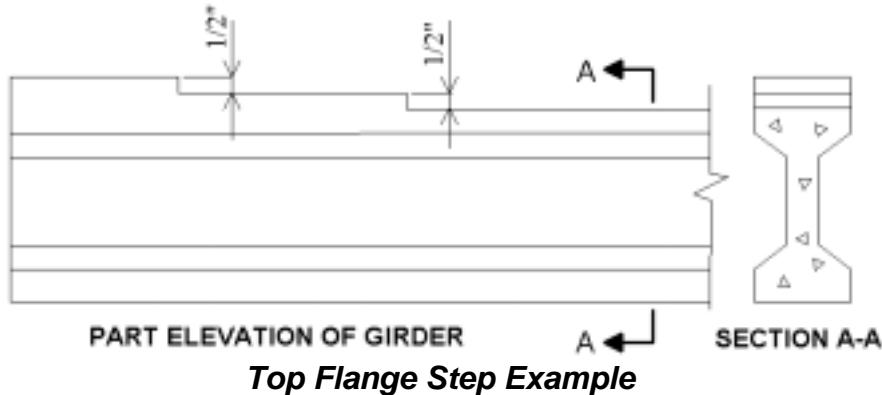

When haunches greater than 2-1/2 inches occur with prestressed panels, steps shall be provided on the girder, as shown on the following page, to keep the haunch between 1 and 2 inches. The minimum step height shall be 1/2 inch with 1/2 inch increments with no limit to the number of steps. If the steps accumulate to 1" or more, adjust the height of the B1 bars in 1 inch increments

Tops of girders, for bridges with superelevations of more than 2 percent, shall be sloped across the top flange to match the superelevation, as shown on the following sheet. The minimum thickness of the top flange shall be the

Theoretical Slab Haunching Diagram Example

standard flange thickness and the overall height at the minimum point shall be the standard girder height.

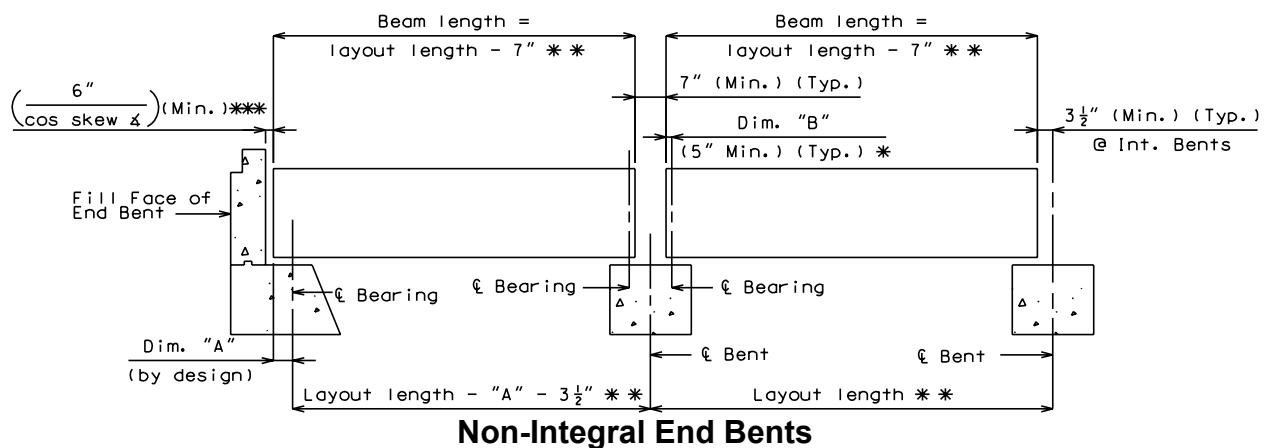

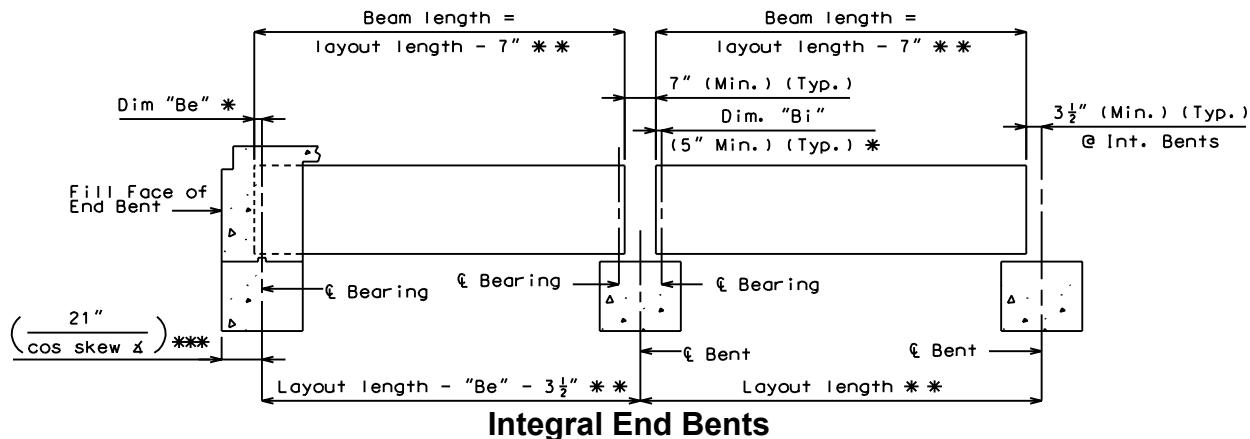

Sloped Top Flange Example

Beam Lengths and Geometric Layout

Tangent Bridges

Beam lengths for end spans of tangent bridges shall be computed using the requirements shown on the following sheet and, if possible, shall be the same length as girders in intermediate spans of equal length as specified on the Design Layout.

Beam Lengths for intermediate spans shall be computed using the requirements shown on the following sheet.

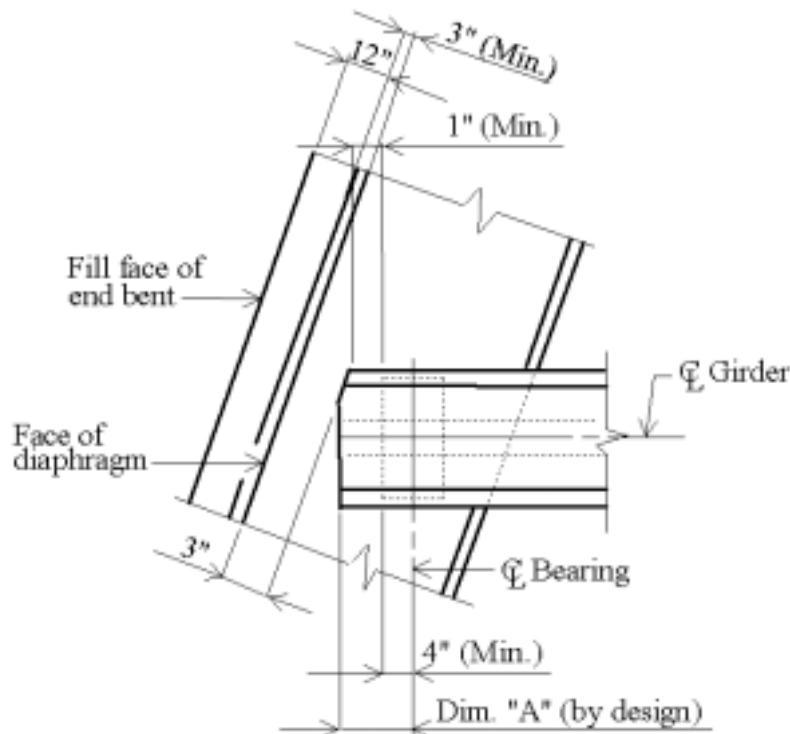

Note: Formulas assume same size bearing pads at end bent and intermediate bents.

* Minimum dimension from edge of bearing pad to end of girder equals one inch.

** Design layout lengths are horizontal lengths. Girder lengths should be adjusted according to grade and shall be specified to the nearest 1/8 inch.

*** For large skews, end bent beam caps may need to be larger to provide edge distance.

**** See Sections 3.30 and 3.35 to determine this dimension.

Part Plan Showing Coping Detail

Note: Non-Integral end bents with skews greater than 40 degrees shall always have girder ends coped. Skews less than 40 degrees shall have girder ends coped on case by case basis. It is preferable to not cope across the web.

Curved Bridges

Layout of any curved structure will have to be done using the coordinate geometry programs available at the time. To layout the bridge, the steps are as follows:

- 1 Start out by laying in the centerline (CL) of the survey curve.
- 2 Locate the tie point of the bridge. This point will usually be on the CL of the survey curve but may be on a baseline which is offset a certain distance to the CL of the survey curve.
- 3 A second tie point may be required if the skew is not measured to the CL of roadway at the bridge tie point. If this is the case, establish the tie point at the specified station and plot the skew line at the required angle.
- 4 Next, on the centerline of structure or baseline curve, locate the station of the CL of bent for each intermediate bent and the fill face for the end bents. Once these points are located, plot lines through these stations parallel to skew line. Normally the layout file will specify that all bents are parallel to the skew line, however, there may be times when the bents are radial or have varying skews.

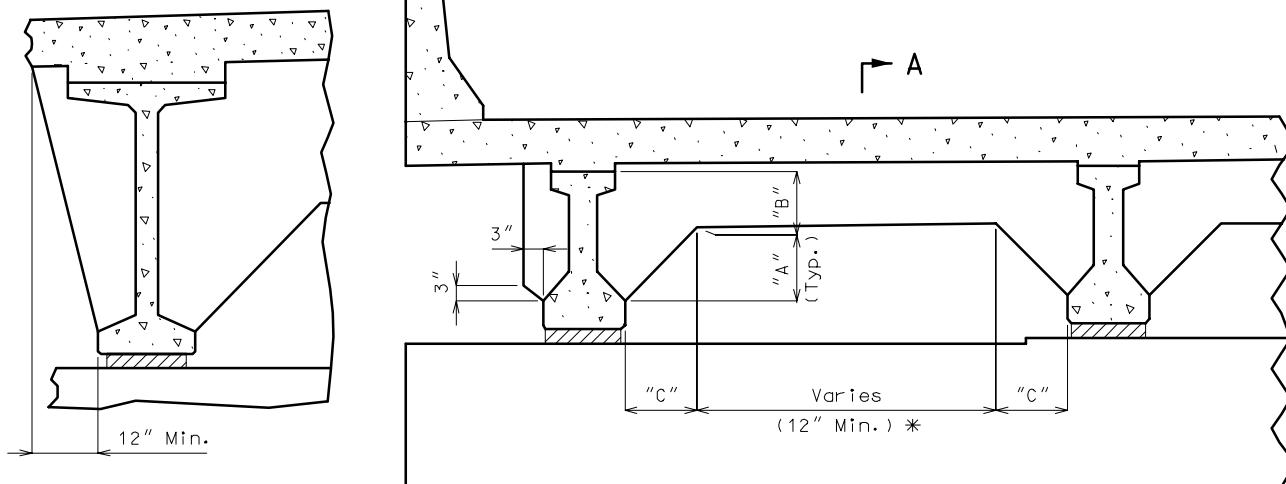

- 5 When locating the stations in the preceding step, the distance between CL of intermediate bents are exactly the layout lengths specified on the file. The end spans however need to follow the procedure for calculating length set forth in this Section. If the layout length of the end span is the same as the intermediate spans, the length of the end span should be adjusted so that the girder lengths are, if possible, equal to intermediate spans with the same layout length.
- 6 When the CL of the intermediate bents and the fill face lines have been added, chords should be drawn connecting these points sequentially. For example if you have a three span bridge, chords should be drawn from the fill face of bent 1 to CL of bent 2, CL bent 2 to CL bent 3, and CL bent 3 to fill face bent 4.
- 7 When all the chords are in, offset each girder in each span parallel to this chord. The perpendicular distance between girders will be the same for all spans, but the skew distance between girders along the bent will vary from bent to bent depending on the skew to the CL at that point. The designer needs to be aware of the fact that at an intermediate bent the distance between bearings on the approaching and leaving span sides will be different distances. These bearings will not line up across the bent and will actually diverge more the farther away they are from the CL of the survey.
- 8 When establishing the CL of bearing points, the designer needs to allow for a minimum of seven (7) inches between ends of girders at the bents while keeping in mind that the girders will be offset and at different skews. If the offset is greater than half the girder flange width, see the Chief Structural Designer. The distance from the end of girder to CL of bearing point should be half of the bearing length plus one inch minimum clearance. Once the distance for CL bent to CL of bearing is calculated, the designer should offset lines by that dimension on either side of the CL of bent. These lines will then be intersected with each of the girder lines to create the bearing points on each bent.
- 9 Between the bearing points at the ends of the girders, quarter points or tenth points need to be established, depending on the girder span. These points will be used in calculating the haunch and bottom of slab elevations for the bridge deck.
- 10 The bridge deck and barrier curbs can be laid in by offsetting the CL of roadway to each side by the proper distance. Curves should be laid in to designate both the inside and outside edges of the barrier curb. These will later be useful in laying in the wings and end bents.
- 11 After the outside edge of slab curves are plotted, the curve offsets need to be found. The intersection point of the outside edge of slab and the CL of each bent or fill face can be connected with chords. The distance between these chords and their partner curves need to be calculated at five feet intervals beginning at the center point of each chord. (Section 2.4)
- 12 Joints are placed in the barrier curb at each bent. These joints are placed perpendicular to the CL of the roadway thru the intersection point of the CL bent and the inside of barrier curb.
- 13 Wing layout length is given on the profile sheets in the layout file. An arc should be struck so as to intersect the inside of barrier curb the specified length from a point at the intersection of the fill face and the inside of barrier curb. This point will mark the end of the wing which is perpendicular to the CL of the roadway.

The vertical curve information needs to be added so the program can calculate the elevations at the desired stations. After this is done, the designer can request any of the following information which will be needed:

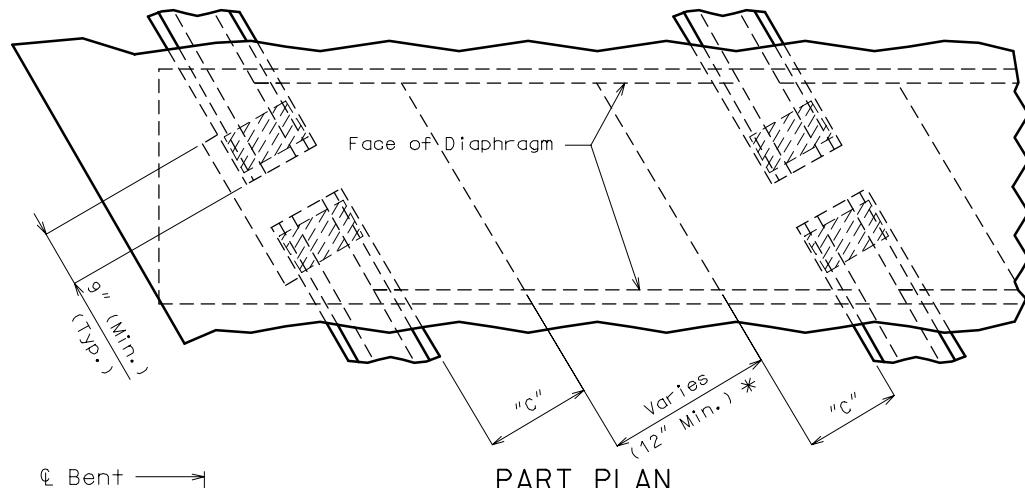

- Stations and elevations of all points
- Offset distances to the chords
- Lengths of girders
- Distances between bearings
- Angles between girders and each bent
- Lengths of bents
- Lengths of barrier curbs between joints
- Minimum vertical clearance (Must lay in lower roadway)

(NOTE: Use only when expansion device connects prestress girder series and steel girder series.)

A protective coating shall be applied to concrete surface exposed to drainage from roadway. Indicate surface to be coated on plans. Epoxy coat all reinforcing steel in the end diaphragms.

(2) For Bulb Tee Girders use 3-#4 Bars in each face.

NON-INTEGRAL TYPE DIAPHRAGM:

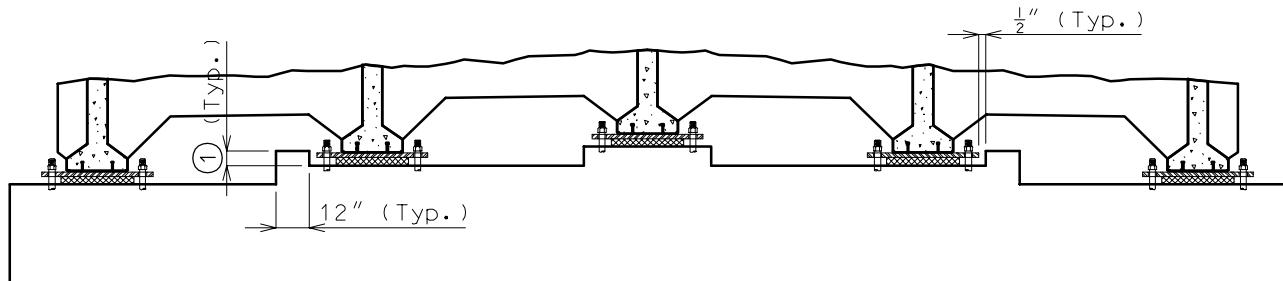

(*) Use only on Type 6 Girder

(1) Use the same clearance as longitudinal slab steel.

SHEAR BLOCKS

MISCELLANEOUS DETAILS

A minimum of two Shear Blocks 12" wide x ① high by width of diaphragm, will be detailed at effective locations on open diaphragm bent caps when adequate structural restraint cannot be provided for with anchor bolts.

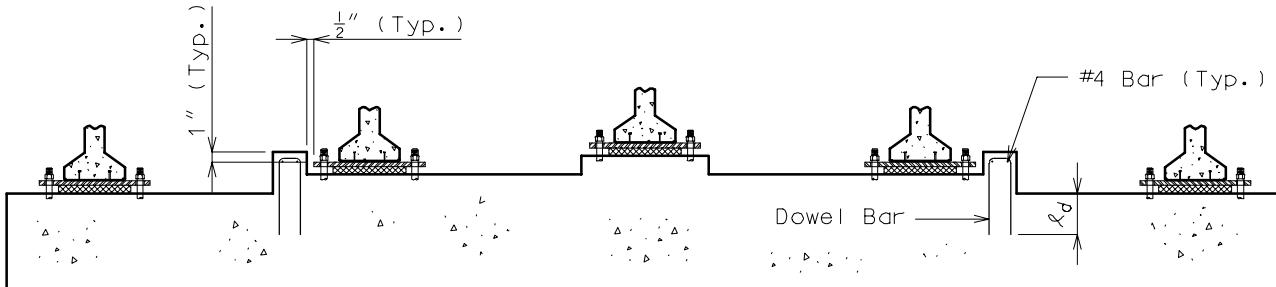

- ① Height of shear block shall extend a minimum of 1" above the top of the sole plate.

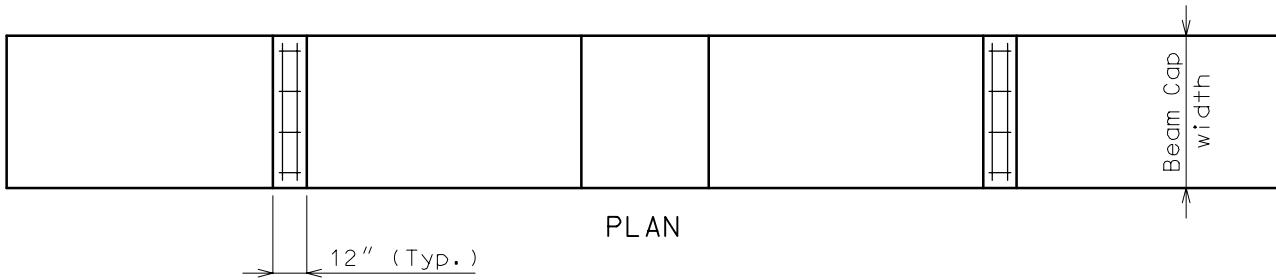

NOTE: Shear blocks may be designed as shown on the following page.

SHEAR BLOCKS (CONT.)
DESIGN EXAMPLE

MISCELLANEOUS DETAILS

ELEVATION

Assumptions:

Shear blocks shall be used at bents with open diaphragms when anchor bolts can not be designed to resist earthquake loading. In such cases, the shear blocks shall be designed to resist the total earthquake load at the bent in each direction (anchor bolts are assumed to have failed).

Design method based on AASHTO 8.16.6.4 (LFD)

Let $f'_c = 3000 \text{ psi}$ $f_y = 60,000 \text{ psi}$ $\text{EQ} = 200 \text{ kips}$

Shear Block width = 12"
length = 42"

Use #6 Bars for shear friction R/I ($A_s = 0.44 \text{ in.}^2$)

Design:

$$V_u = (\text{EQ})/R \text{ where } R = 0.8 \quad V_u = (200 \text{ kips})/0.8 = 250 \text{ kips}$$

$$V_n = \frac{V_u}{\emptyset} = \frac{250 \text{ kips}}{0.85} = 294 \text{ kips} \leq \begin{cases} 0.2 f'_c A_{cv} = (0.2)(3 \text{ ksi})(12'' \times 42'') = 302.4 \text{ kips} \\ 0.8 A_{cv} = (0.8)(12'' \times 42'') = 403.2 \text{ kips} \end{cases}$$

where A_{cv} is shear area of shear block

$$A_s = \frac{V_n}{(f_y)(\mu)} \text{ where } \mu = 1.4 \lambda \text{ and } \lambda = 1.0 \quad \left(\text{Note: Use } \mu = 1.0 \lambda \text{ for retrofits} \right)$$

$$A_s = \frac{294 \text{ kips}}{(60 \text{ ksi})(1.4)} = 3.5 \text{ in.}^2$$

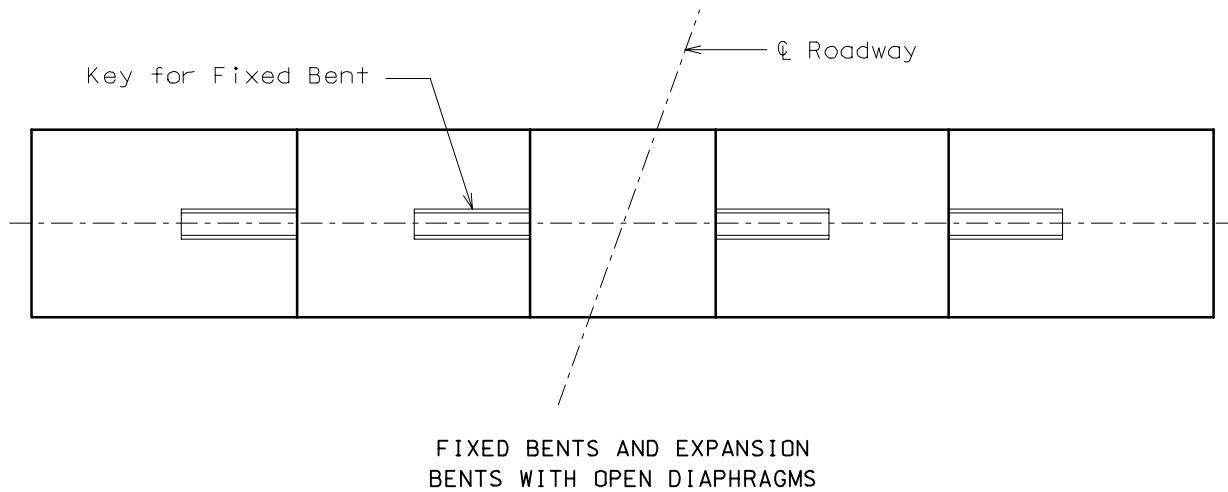

$$\text{Number of bars req'd} = \frac{3.5 \text{ in.}^2}{(2)(0.44 \text{ in.}^2)} = 3.98 \text{ bars}$$

Use 4-#6 Bars for each shear block with $\lambda_d = 16''$

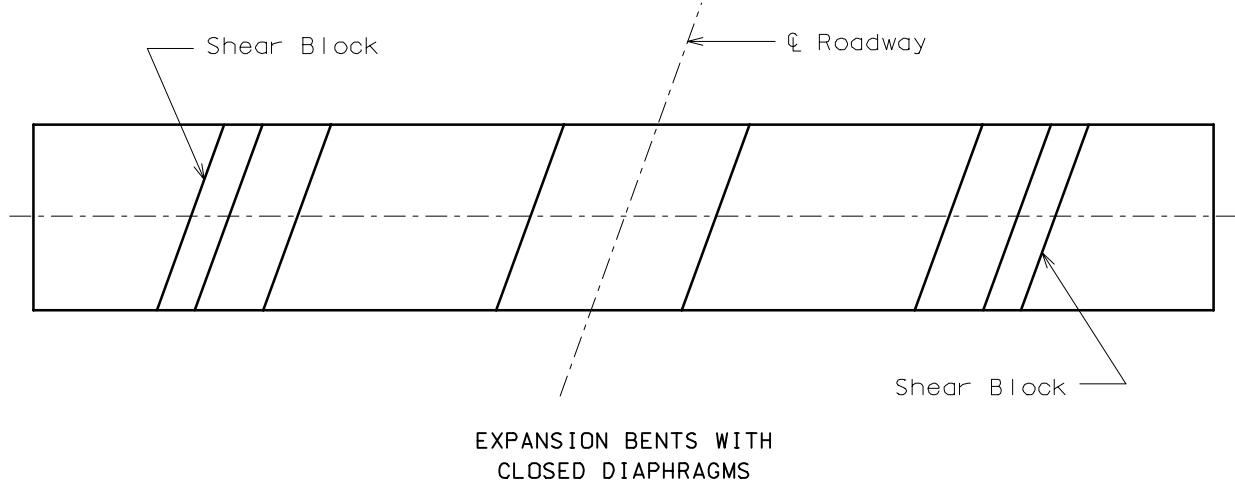

NOTE: Same procedure is valid for closed diaphragms at expansion bents.

BENT STEPS

Miscellaneous Details

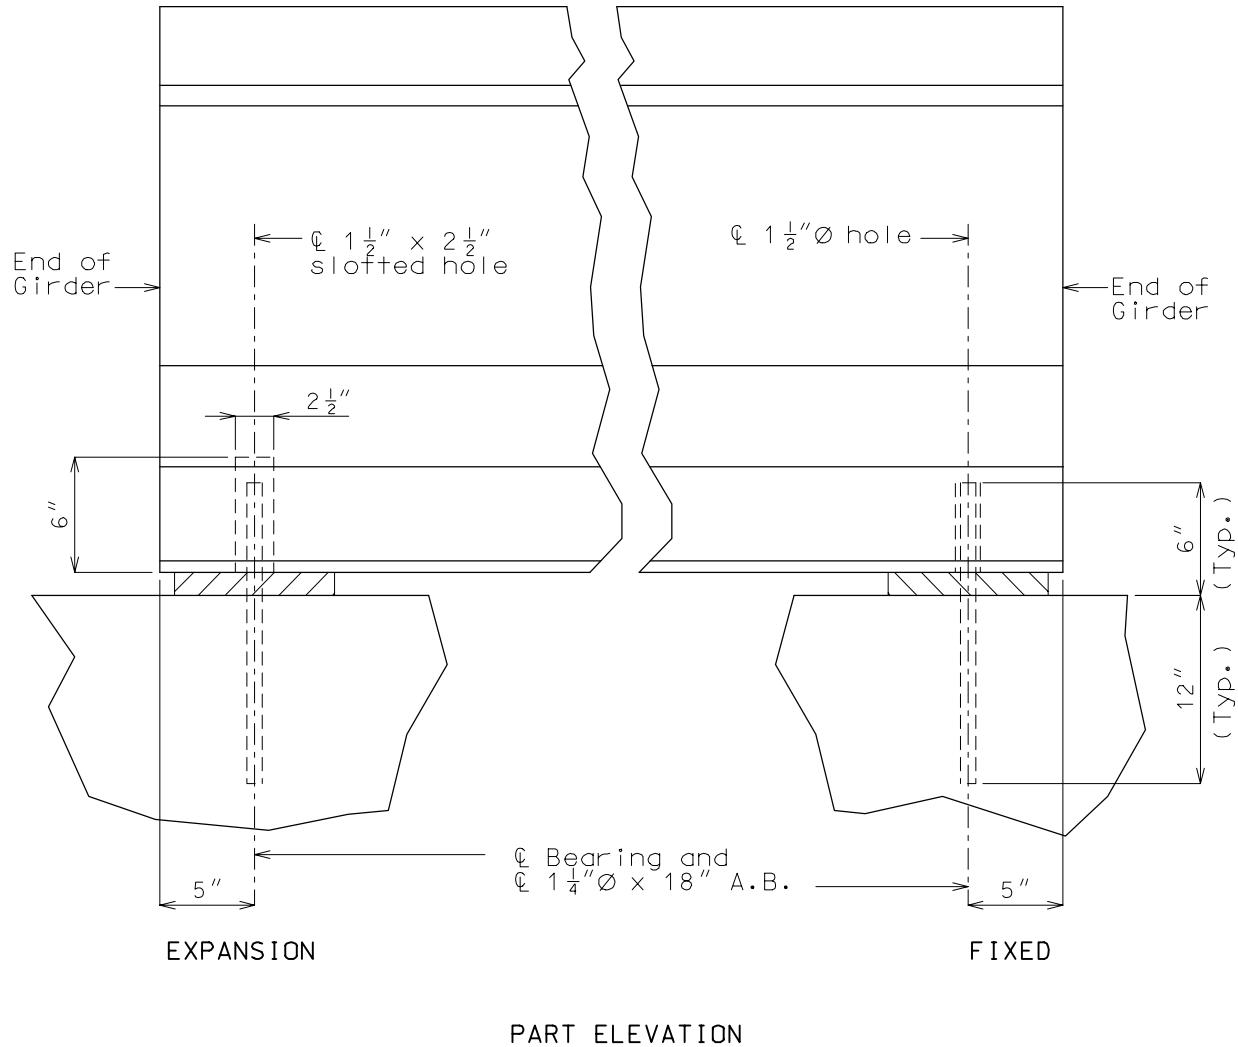

NOTE: For Fixed Bents and Expansion Bents with open diaphragms, the steps or haunches and end of keys (when applicable) should be normal to the length of cap.

NOTE: For Closed Diaphragm Expansion Bents, the steps or haunches shall be detailed parallel to the centerline of roadway.

For Integral End Bents the steps may be skewed due to stirrups being placed parallel to centerline of roadway.

Shear Blocks for Expansion Bents with Closed Diaphragms shall be detailed parallel to the centerline of roadway. Shear Blocks used in conjunction with sole plates and anchor bolts shall be detailed parallel to the edge of sole plate.

Note:

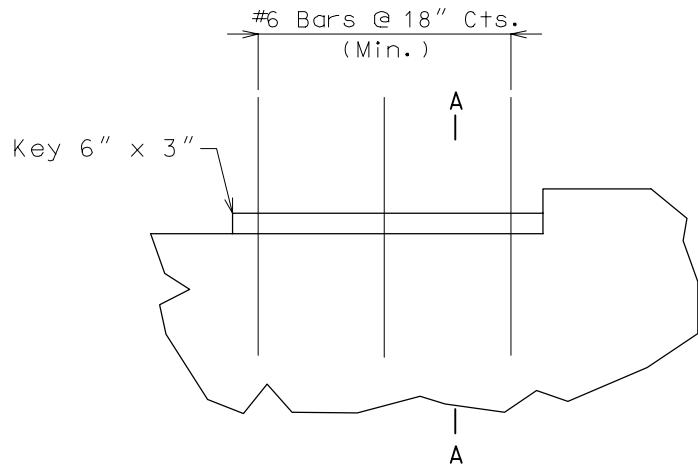

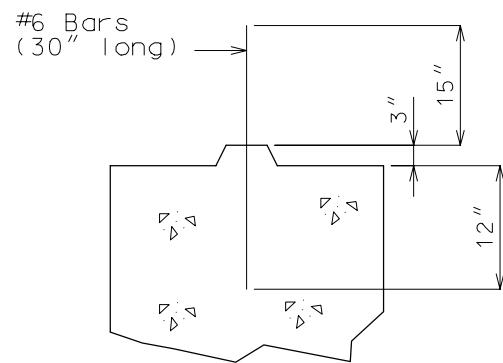

It is permissible for the reinforcing bars and or the strands to come in contact with the materials used in forming A.B. holes.

If A.B. holes are formed with galvanized sheet metal, the forms may be left in place.

Hole ($1\frac{1}{2}'' \varnothing$) to be grouted with expansive type mortar meeting the requirements of Section 1066 of Standard Specifications.

DOWEL BARS

Miscellaneous Details

PART ELEVATION
(FIXED BENT) (*)

SECTION A-A (*)

(*) Details shown are for SPC A and B only.

Dowel bars shall be used for all fixed intermediate bents under prestressed superstructures.

Seismic Performance Category A:

Use #6 Bars @ 18" Cts. for dowel bars.

Seismic Performance Category B:

Dowel bars shall be determined by design.
(#6 Bars @ 18" Cts. minimum)

Design dowel bars for shear using service load design.

Allowable stresses are permitted to increase by 33.3%
for earthquake loads.

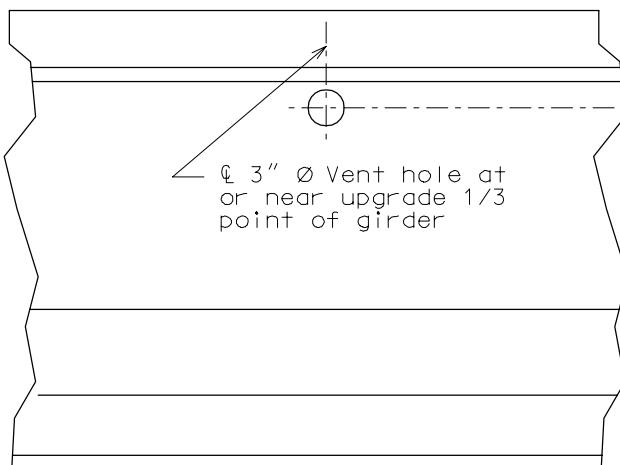

Seismic Performance Categories C & D:

See Structural Project Manager.

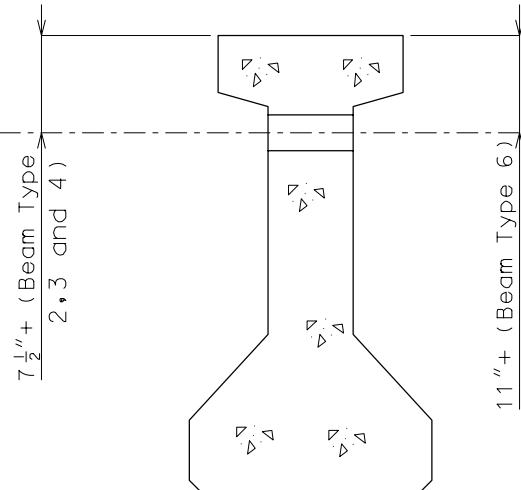

VENT HOLES

Miscellaneous Details

Note: Use vent holes on all stream crossing structures.

PART ELEVATION OF GIRDER

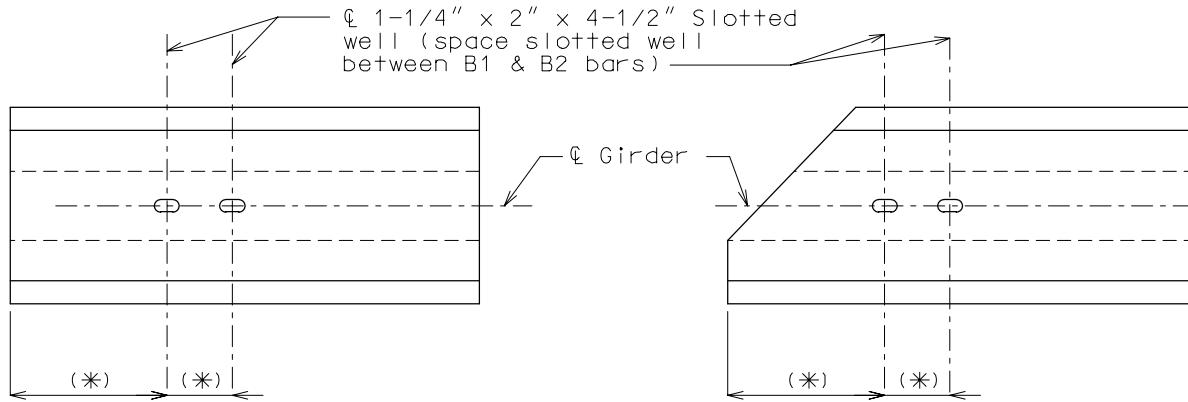

PART SECTION NEAR VENT HOLE

Note: Place vent holes at or near upgrade 1/3 point of girders and clear reinforcing steel or strands by 1-1/2" minimum and steel intermediate diaphragms bolt connection by 6" minimum.

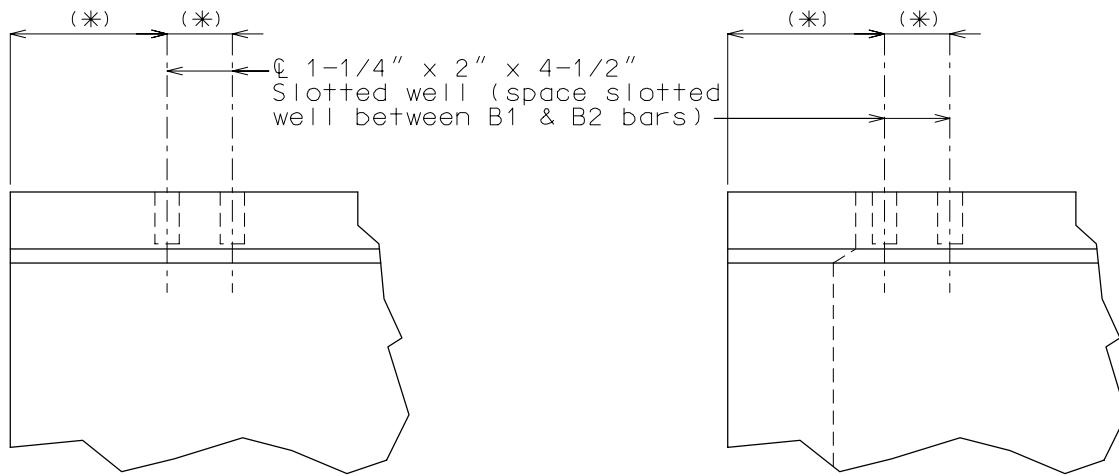

EXPANSION DEVICE SUPPORT SLOTS

Miscellaneous Details

Used with preformed compression joint seal, flat plate, strip seal or finger plate expansion devices.

PART PLAN OF P/S CONC. I-GIRDER @ EXP. DEVICE END

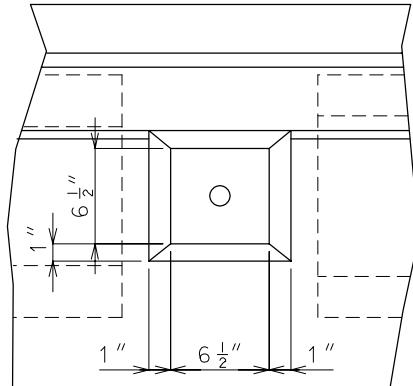

PART ELEVATION OF P/S CONC. I-GIRDER @ EXP. DEVICE END

(*) Show these dimensions on the P/S concrete girder sheet.

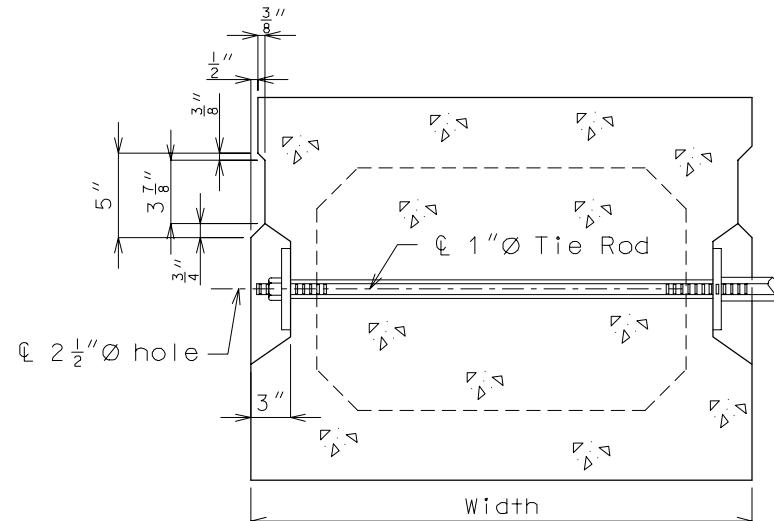

TIE ROD DETAILS AND LOCATIONS

Precast Prestressed
Concrete Box Girders

Note: 1"Ø Tie rods, sleeves and nuts shall be A307.

ELEVATION

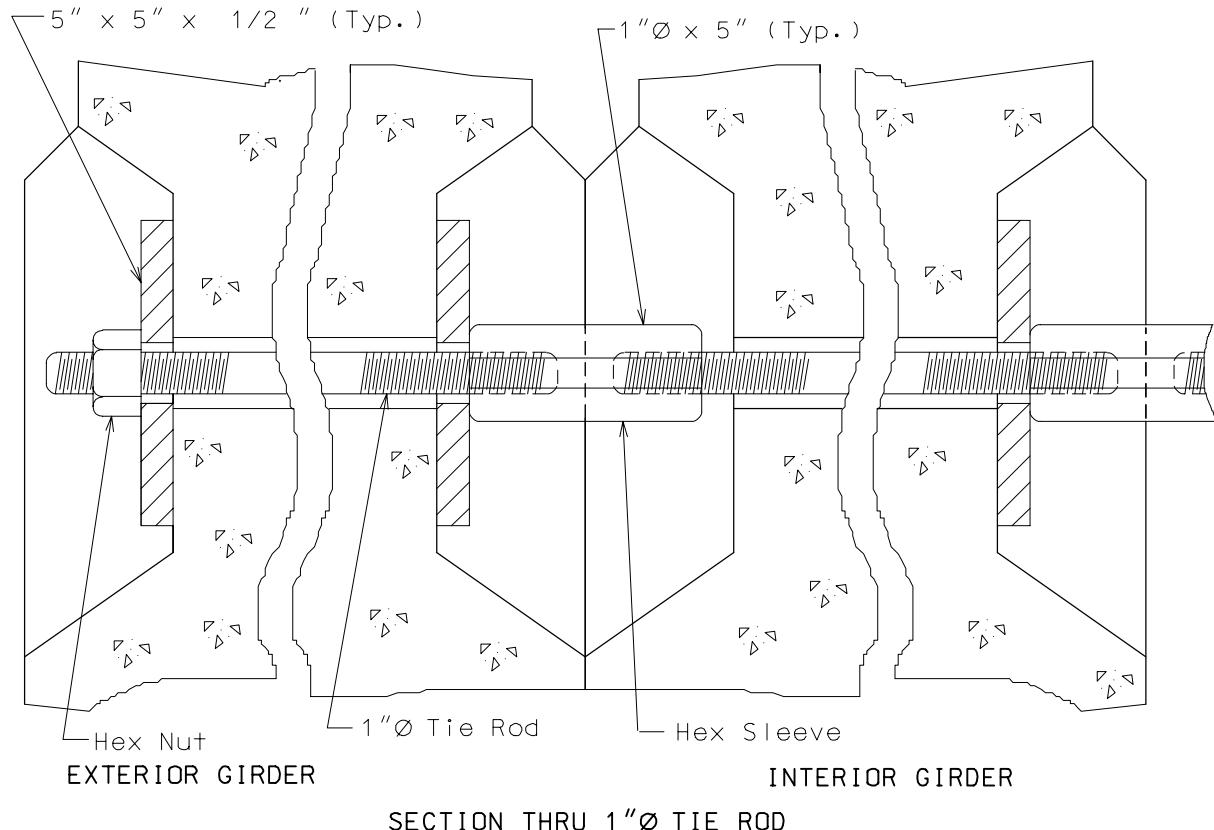

SECTION @ 1"Ø TIE ROD
EXTERIOR GIRDER

Tie Rod: 1"Ø x (width girder -1") with 4" thread each end.

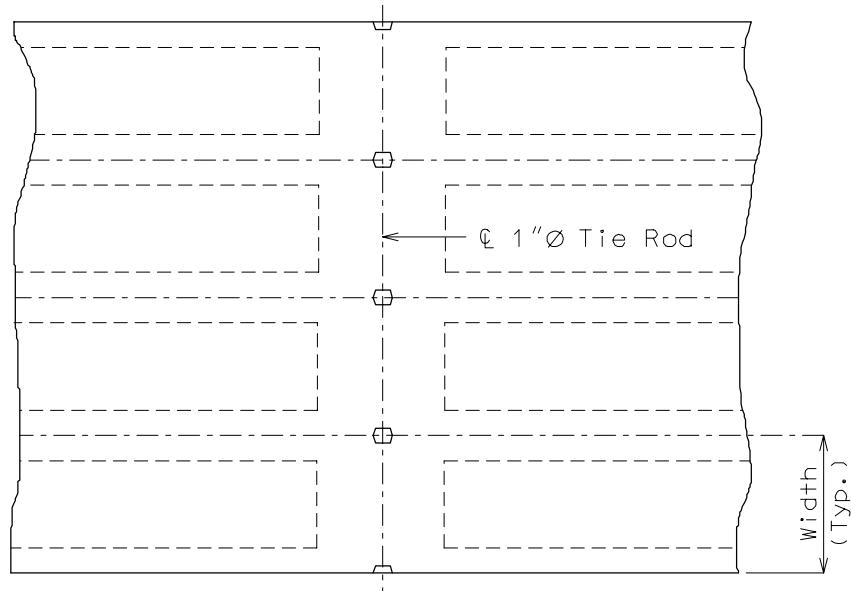

Sleeves: 1"Ø x 5" full threaded hex sleeve.

Washer Plates: 5" x 5" x 1/2" Plate with 1-1/8"Ø hole.

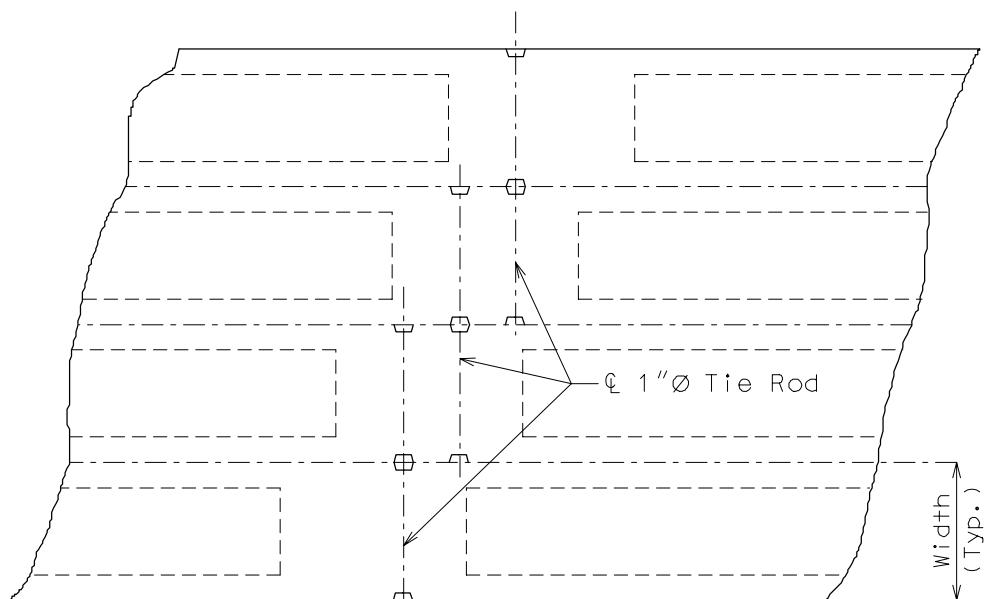

Nut: 1"Ø American Std. Heavy Hex Nut.
